Abstract

Improving the graduation rate of engineering students at any engineering college is a challenge. A new critical thinking tool that is gaining widespread use in lean manufacturing may be used by engineering colleges to guide their efforts in improving the graduation rate of their engineering students. This tool is known as the strategic X-matrix. An example using the strategic X-matrix will be presented.

Research Question

Using critical thinking, how does an engineering college improve its student retention?

Methodology

The ideas of lean six sigma were used to enhance critical thinking for the objective of improving engineering student retention. Using six sigma DMAIC, first the overall objectives must be defined and the success indicators must be proposed and measured. The Strategic X-Matrix enhances critical thinking for this definition. Analyze-Improve-Control can then be used to improve student retention. The X-Matrix enables an improved thought process for developing the improvement priorities and success indicators for higher graduation rates.

Example

An hypothetical example for an engineering college is proposed using the X-matrix. Read it by starting at the bottom and reading clockwise.

My recent PhD research at U-M showed that Freshman retention was influenced by:

- High School Preparation
- Concern about Financial Needs
- Confidence in Math ability
- Interest in Study Abroad Program
- Enrollment in a Survey Course on Engineering Careers

Improving these characteristics were included as Tactical Improvement Priorities

Four Strategic Objectives were Considered:

- Improve the Graduation Rate
- Increase the Minority and Female Faculty
- Obtain Feedback from all stakeholders for education of engineering students
- Increase Research in Energy Innovation
