

Living on

The Vineyard isn't alone when it comes to dealing with issues of erosion, sea level rise, and the perils of living so close to the ocean.

the edge

Billingsgate Shoal in Cape Cod Bay is a sandy relic of the former island; still visible just below the failed revetment at top left is the foundation of the Billingsgate Lighthouse, above, built in 1898.

Rounding Jeremy Point into Wellfleet Harbor, mariners in Cape Cod Bay are cautious. There, marked on all the charts, are the sandy fingers of Billingsgate Shoal – or, as it was once known, Billingsgate Island. In the mid-nineteenth century, the island was a mile long, a half-mile wide, boasted thirty homes, a lighthouse, schoolhouse, and a flourishing fishing fleet. Fed by a steady supply of sand from the inner forearm of the Cape, Billingsgate was for centuries terra firma, a charming coastal haven welcoming sailors to Wellfleet. When the dynamic forces that kept the island awash in sediment shifted, it began to disappear. When the community desperately added a breakwater made of riprap to protect its lighthouse, the island all but vanished overnight. Today that breakwater is visible at low tide, the last vestige of an island that was a familiar beacon of the inner Cape for centuries.

The Vineyard is safe from the fate of Billingsgate – but only for a time. Since the end of the ice age, the pile of glacial outwash and sand known as Martha's Vineyard has been wearing away from its original shoreline on the continental shelf some eighty miles south, to its present, temporary boundary. The Cape and Islands will eventually erode away to nothing – they were never meant to stick around.

This is, of course, the geological perspective. In the meantime Vineyarders are grappling with what happens when manmade structures and property lines pop up along, and run afoul of, this steadily retreating border.

OPENING SPREAD: ALISON SHAW; LEFT: CHRISTOPHER SELUFERT

“This will, I think, become one of the defining issues of the twenty-first century,”

says Andrew Kahrl, a fellow at Harvard’s W.E.B. Du Bois Institute and a professor at Marquette University in Wisconsin, where he specializes in the history of beaches and coastal development. “Martha’s Vineyard fits into a broader pattern.”

According to a 2000 study by the Federal Emergency Management Agency (FEMA), the United States can expect to lose 87,000 structures to erosion within sixty years. That works out to 1,500 structures lost each year, at a cost to homeowners of \$530 million per year. In Massachusetts alone, 36,000 homeowners live within five hundred feet of the shoreline.

“There’s this divide between climate scientists and coastal geologists, and then policy makers and private property owners. In many respects, those two are speaking over each other,” says Kahrl.

WAYNE SMITH

Waterfront property becomes too literal: This Chilmark home teeters on the edge of the south shore after last fall's big storms.

On Chappaquiddick, a family is sinking millions into a massive engineering project to buy a few more precious years for their house. In Oak Bluffs, eroding seawalls and bluffs threaten infrastructure, leaving residents to wonder who will pay for costly repairs. The Vineyard's vulnerable geology, coupled with the specter of sea level rise, means that the sort of drama currently unfolding around the Island will only become more common.

UNDERSTANDING EROSION

The particular phenomenon of coastal erosion currently besetting the Vineyard is staggeringly complex. First, as mentioned, the Vineyard is made mostly of sand and glacial till, and wave action has been steadily eroding the Island since its relatively recent creation.

Second, the Vineyard might actually be sinking. When the glaciers receded, the landmass bounced back up, like a seat cushion after the removal of a rear end. That rebound peaked thousands of years ago, and now the Island is settling back down again. (Alaska, which was under glaciers more recently, is still rising.)

Third, the waters around the Vineyard are rising – almost a foot in the past century, according to tide gauges. But sea level rise is not a simple affair. The oceans are rising both from the onrush of glacial meltwater as well as from thermal expansion as the waters warm (in April, the National Oceanic and Atmospheric Administration [NOAA] announced that sea surface temperatures in the Northeast Atlantic hit a 150-year high in 2012). And according to a study by the United States Geological Survey published last fall in *Nature Climate Change*, sea levels between North Carolina and Newfoundland are rising three to four times faster than the average global rate, due to the slowing of the Gulf Stream, which is tilting the ocean back toward our shores.

In Aquinnah, where the town is scrambling to move its historic lighthouse back from the edge of a crumbling cliff, another kind of erosion altogether is at work: Rain is slowly washing the clay down into the ocean.

Of course all of this erosion is nothing new. Recently in Chilmark, where several homes are imperiled, a lifelong Islander recounted how he had attended a wedding “out there,” pointing to an imaginary point a hundred feet offshore. There is an uneasy sense that things have been picking up in recent years.

Top, sand-stuffed coir bags, an alternative to structural revetments, line the Schifter property at Wasque Point on Chappaquiddick's southeastern tip. Bottom left, the property lost 150 feet last year alone, prompting the family this year to relocate the main house, right, guest house, and pool.

RAY EWING

RAY EWING

At the end of May, The Trustees of the Reservations superintendent Chris Kennedy surveys the Wasque swimming beach, a landscape utterly transformed by erosion, driven mainly by the forces at work since the breach of Katama Bay in 2007. The tip of Norton Point now extends to run parallel to the south-facing shore of Chappaquiddick. We stand at the edge of a hundred-yard-wide, debris-strewn sandy beach, protected by a lagoon with wave-blasted sandbars, behind which the tide pushes the water in a gentle river in and out of Katama Bay. A year ago the same beach was an impassable sheer cliff face with waves crashing against a snarl of oak trees that had toppled from above. The changes have rendered maps of the area useless.

“When I started two decades ago, the beach started six hundred feet from where you and I are standing, beyond those sandbars,” Kennedy says, gesturing towards the horizon. “At Wasque Point it was more like eight hundred feet. I remember in my first couple of years you would have 150 to 180 cars on the point. Now it can hold maybe one or two cars.”

Kennedy says that Wasque’s latest erosive episode likely had little to do with sea level rise or climate change, because it is almost identical to previous breach openings.

But after a winter that saw the beach lose twenty feet in a single storm, he’s apprehensive about the future.

“Anecdotally this winter we had more storms than I can ever recall in my twenty-five years,” he says. “It does invite the question: Did climate change have anything to do with it? The answer in the short term is no. But in the long term we should expect to see more severe winter storms.”

Past a bewildered gray seal pup, the beach narrows at its eastern tip near Wasque Point, culminating in what looks like a mountain of enormous sausage links. These are essentially giant sandbags installed to help protect the six-year-old, 8,000-square-foot house of Washington, DC-based private equity partner Richard Schifter, who has lost 150 feet of shore-front property in the last year alone. But the coir bags are not as sturdy as they look. Made from coconut husks and filled with sand, they are designed to steadily leak away all of their sand, so as to supply sediment to downdrift beaches – acting like an artificial coastal bank, and buying time for the Schifter house as it is relocated 275 feet back from the deteriorating shoreline. The bags are increasingly showing up in coastal areas where

public officials have learned from decades of misguided attempts to save beachfront property from erosion; armoring the coast with engineered structures has effectively destroyed the beaches they were meant to protect.

NATURE’S WAY

While the rapid loss of beach at Wasque Point may be deeply troubling to the Schifters, it’s a source of endless fascination to Woods Hole Oceanographic Institution coastal geologist Gregory Berman, who has surveyed the area several times.

“I love going out there,” he says. “It’s the most dynamic spot in Massachusetts right now. At one point this winter it was losing feet a day. You just don’t see that.”

The glaciers reached their furthest extent, the so-called terminal moraine, a little more than twenty thousand years ago. There they continuously melted, dumping material along the line that would form the spines of Martha’s Vineyard and Nantucket. After a quick retreat and pause along the spine of the Cape, the glaciers hightailed it north. Long before it was a buzzword, sea level rise was a very real phenomenon: Over the past several millennia the oceans have risen about four hundred feet.

“As that land has been submerged and the beaches have been rolling back on the islands, they’ve been able to do it because people haven’t been in the way,” says Berman. “If someone had built a revetment or a seawall around their house

ISTOCKPHOTO.COM

Sand from the Bahamas replenishes Miami's densely built-up beaches.

five thousand years ago, they'd be fifty miles offshore by now."

What we were given by the glaciers is what we've got, and we're not going to get any more. This isn't the case for other, luckier, ocean-facing communities.

"In the Carolinas you have a watershed that supplies a lot of sediment into the rivers and out through the inlets along the beaches, so there's new material entering the system," he explains. "Here you actually have to erode the coastal banks, the dunes, or the beaches themselves to keep material on the beach."

In such a system – where the beach itself has to erode to supply sand elsewhere – when a homeowner armors their property with rocks or seawalls, the demise of the beach and the beaches around it are inevitable. It might seem counterintuitive, but unimpeded natural erosion in these parts is generally a good thing. Still, the record of failed beach armoring projects in the region is impressive, if entirely predictable.

In Chatham, after a breach of Nauset Beach in 1987, homeowners north of the breach, alarmed by the quickening pace of erosion, built a revetment in front of their houses along shoreline owned by the US Fish and Wildlife Service. The Fish and Wildlife Service approved the plan, provided the homeown-

ers maintained a six-foot-wide sandy beach. It quickly became apparent that such an aim was futile. Today, in place of a public beach, there is a long stretch of stone lapped by the Atlantic. Mashpee has similarly lost a large stretch of its Nantucket Sound beach after revetments were installed to protect houses.

Seawalls and revetments are doomed to eventually fail. When a seawall beach erodes away, as it inevitably does, the waves begin to hit the seawall directly. The energy from this direct strike is damaging enough, but it is also reflected sideways (scouring adjacent beaches) and downward (scouring the sand underneath the wall until it becomes unstable). Beach habitat disappears, as does public access, and, according to one study, while property values for the first row of houses on the water remain intact, those behind it suffer.

The South Shore town of Marshfield draws parallels to Oak Bluffs, where the beach adjacent to the Steamship Authority pier has disappeared, the seawall is crumbling, and the engineered East Chop bluffs are becoming unstable. Marshfield is coming to grips with the financial ramifications of a heavily armored coastline. In April residents voted to spend more than \$4 million to repair a thousand feet of crumbling seawall guarding a row of houses perilously close to the water. Other than a wholesale abandonment of the coast, there is little choice for communities like Marshfield that built out their waterfront before the age of smart coastal planning.

On Martha's Vineyard, town boards have, for the most part, rejected beach armoring in recent years, most notably in West Tisbury, where town officials struck down a proposal for a 135-foot revetment at the Tisbury Great Pond estate of Wall Street financier Wesley Edens.

Imported sand endangers delicate ecosystems, and Atlantic green turtles.

SARAH OKTAY

Artificial nourishment is less economically sustainable on rural, private properties; this area of Nantucket shoreline loses twelve feet of beach a year.

PLENTY OF SAND IN THE SEA

But there are ways to fight Mother Nature other than fortifying the coast. Nourishment, or constantly supplying the beach with sand that is trucked or shipped in, is one way to stem the tide of erosion. The poster children for beach nourishment are Miami, whose coastline is entirely artificial, and the New Jersey shore, which is coming to grips with how much to redevelop in the wake of Hurricane Sandy.

“In New Jersey or Florida you have a huge property-tax base because the condominiums and buildings are stacked tall and densely packed. The Army Corps of Engineers will do an analysis to see: Is it worth building a sacrificial dune along a twenty-mile stretch? You need that kind of density to make it economically reasonable,” says Berman.

“You guys don’t have that,” he adds about the Vineyard. Even if it were economically feasible, beach nourishment comes with other, less obvious complications. Florida is arguably the most important state in the country for nesting endangered sea turtles. The gender of sea turtle hatchlings is exquisitely sensitive to sand temperature, and imported sand that is the wrong color can absorb more or less heat, throwing an artificial variable

at an already vulnerable population. Florida also imports huge quantities of sand from the Bahamas, stirring resentment in that island nation.

Closer to home, beach nourishment projects have run into permitting trouble, notably on Nantucket,

where Codfish Park on the eastern shore has seen more than twenty houses fall into the sea in the past two decades. Amazingly, the shoreline of Codfish Park has actually accreted overall by a few feet since the mid-1800s, a testament to the beach as a place of dynamic equilibrium, always eroding and accreting without regard to property lines and artificial borders. What went wrong was that Nantucketers built entire rows of houses during an accretional cycle that lasted until the 1950s,

only to see that land mercilessly churned up and returned to the sea during an erosive period that has lasted until the present day. Where two rows of houses in Codfish Park stood as recently as the mid-1990s, a natural dune has re-formed and taken their place.

Sarah Oktay is the director of the University of Massachusetts Nantucket Field Station, the chair of Nantucket's newly formed coastal management planning committee, and a member of the Nantucket Conservation Commission. The commission has repeatedly blocked the efforts of the Siasconset Beach Preservation Fund, a group of private homeowners who have put forward a number of elaborate proposals to save their slice of heaven on the island's eastern shore. Oktay can sympathize: One of the buildings on her own property is

Nantucket scientist Sarah Oktay has firsthand experience with erosion.

thirty-nine feet from an eroding bluff that lost ten feet in just a few months, while another has sunk into an adjacent marsh and is condemned.

She reports that the conservation commission receives one or two proposals a week for erosion control projects. But it was the Siasconset Beach Preservation Fund's large-scale beach nourishment proposal that was perhaps the island's most contentious. The private homeowners group proposed spending \$25 million to dredge sand from three miles offshore and dump it on a three-mile stretch of rapidly eroding beach.

"A lot of the year-rounders and old-timers were like, 'Listen, we always put crappy homes by the shore,'" she says.

"A lot of them thought it was hubris – that you shouldn't build too close to the shore in the first place."

But it wasn't hubris that sunk the Siasconset Beach Preservation Fund's plan to save their homes; it was the concerns of fishermen, who formed a nonprofit organization to fight the plan. Whereas off of Florida there exists an enormous industry of sand miners, with armies of boats panning the seafloor with side-scan sonar and multi-beam bathymetry looking for new beds of sand to exploit, in Massachusetts offshore sand mining is practically taboo. The state Division of Marine Fisheries has balked at sand mining for even small-scale nourishment projects.

"For a long time the state has said, 'No. Everything's fish habitat and you can't prove that it's not,'" says Berman. "It's impossible to do unless some state players go along, and so far they haven't."

Underwater, just off of Siasconset Beach, is a complex seafloor habitat of cobblestones and larger rocks that were left behind when previous coastal banks eroded. Fishermen complained that by dumping more than 2.6 million cubic yards of sand on the beach, as the homeowners proposed, they threatened to bury one of the most important fishing grounds. Ultimately the Beach Preservation Fund dropped the proposal. Oktay, a chemical oceanographer, says that beach nourishment is not a sound solution for a coastal environment as rich as that of the Cape and Islands.

"If I look at my beach right now, I see willets, plovers, sand pipers, oystercatchers, and tons of seagulls feeding on mole crabs and insects that are on or below the sand," she says. "If I took sand from somewhere else on the island and put it five feet deep, it would kill everything. If you're talking Miami or Disney maybe you want a sterile beach, but on Nantucket, it's a very healthy, active beach. Why make it fake?"

Still, there are successful beach nourishment programs even on the Vineyard. The Cow Bay Association in Edgartown, a private homeowners group, buys sand from the town of Oak Bluffs to

Facing, clockwise from top left: Crumbling cliffs are cordoned off at Wasque; shifting sands along the south shore blur the boundaries between the Island's great ponds and the Atlantic Ocean; shorebirds exist within a fragile ecosystem at water's edge; nor'easters, such as this one off East Chop, are a major cause of coastal destruction; plans are underway to relocate the Gay Head Light away from eroding cliffs.

CLOCKWISE FROM TOP: LEFT: IVY ASHE; NEAL RANTOUL; JEFF MACHOLZ; ALISON SHAW; DANA MORRIS

combat erosion near Eel Pond. That sand is dredged from a channel in Sengekontacket Pond, part of an effort to improve water quality for the town's shellfish beds. But even that project has endured an endless slew of permitting hurdles by the National Marine Fisheries Service, the Army Corps of Engineers, and the Wampanoag Tribe, and beach nourishment is unlikely to become a panacea for other erosion hotspots on the Island.

POLITICS IN PRIORITIES

While it's impossible to rewind the past half-century, when a newly prosperous and leisured postwar America rushed headlong and often heedlessly toward the sea, communities can still plan for the future. Coastal hazards specialist Maria Honeycutt at the NOAA Coastal Services Center in Silver Spring, Maryland, works with state and local governments providing data on the potential impacts of coastal erosion, storm surges, and sea level rise. But ultimately, she says, it is up to the communities themselves to move forward prudently.

"I think it's safe to say people are seeing the cost associated with responding to these disasters and are realizing that it's clearly just not going to be sustainable," she says. "There's this idea that's gaining acceptance that it's better, and much less costly, to prepare than to respond again and again."

ALISON SHAW

COURTESY MARIA HONEYCUTT

Maria Honeycutt of NOAA advises governments on coastal changes. Here she stands by the "Wave," another erosion phenomenon, in the Paria Canyon-Vermilion Cliffs Wilderness near the Utah-Arizona border.

This planning is already quietly underway in Oak Bluffs where, thanks to the help of a grant from the state's Coastal Zone Management's Storm Smart Coast program, the town has amended its zoning to discourage building in areas most likely to be flooded under higher seas. Insurance companies, with perhaps the most to lose, are also coming around.

"For the first time you're actually seeing insurance companies with climate experts on their staff," says Honeycutt. "Insurance companies, particularly reinsurance companies, have been at the forefront of understanding the potential exposure of their portfolios to climate impacts, improving their risk models, which affects their pricing."

In the meantime, one of the least bad options is a retreat from the sea. While the Schifters' move has been ridiculed in some circles for its futility and for its impact on the surrounding environment, moving back is the way Cape and Islanders have historically responded to a ceaselessly marching shoreline.

"I think one of the main problems is that we really overvalue our shorefront property," says Berman. "If we really took into account the risk of living on the coast, it would not be very expensive to live there – people shouldn't want to."

When the original eighty-eight lots of Siasconset were drawn up at the turn of the last century, the Nantucket developer designed the parcels to allow homeowners to retreat inland.

The diminishing cliffs of Chilmark's Lucy Vincent Beach are embedded with Island history, from pre-European artifacts to megalodon teeth, below.

In subsequent decades these parcels were subdivided and sold, leaving new property owners little place to go when the sea inevitably returns to collect its sandy tribute.

"What the shape of a beach is today is not what it will be tomorrow or next year," says Kahrl. "That's the purpose beaches serve. They can't be tied down or subdivided into parcels of land. That goes against the entire nature of what they are."

"Life on the shore is transient," says Oktay. "Appreciate the time you have."

A PERSPECTIVE ON TIME

After an off-season of storms that ripped away at the cliffs at Chilmark's Lucy Vincent Beach, I went to see what was left in May. They were calved and splintered, jutting into the ocean like an earthen bowsprit. Underfoot, torn from the cliffs by the Atlantic, was an umber chunk of clay with a smooth gray stone embedded in it. A closer inspection of the stone revealed serrated

edges and polished enamel. After a painstaking excavation I had in my hand the five-inch tooth of a megalodon, still sharp enough to cut me, which it did – its first taste of flesh since a prehistoric whale perhaps, millions of years ago.

The animals were likely similar to modern great white sharks in appearance, only bigger. Much bigger. While white sharks rarely reach twenty feet in length, the largest megalodon may have topped seventy feet. Megalodons lived from roughly 28 million years ago to 1.5 million years ago.

Tooth specimens are preserved in clay of the sort found in Chilmark and Aquinnah, but digging for fossils along the cliffs is illegal. This megalodon remnant, rescued from the tide, is from millions of years ago. Martha's Vineyard, comprised mostly of sand and glacial till deposited some twelve to fifteen thousand years ago, is a youngster in comparison, and one whose shape is constantly evolving. ♦
