True/False-Explain. Respond to the following statements by *explaining why they are true or false*. For each statement, a complete and correct explanation is worth 10 points. No partial credit will be awarded for stating TRUE or FALSE without explanation.

1. (10 pts.) Multinational firms, which make up less than one percent of US manufacturing firms, account for almost 75 percent of R&D spending. This fact suggests that multinational firms tend to have strong ownership advantages.

TRUE. The concentration of R&D in multinational firms is evidence that “ideas” are important parts of these firms. These ideas may manifest as patents, copyrights, or trademarks, or they may be intangible assets. These assets generate an ownership advantage: The assets are valuable enough abroad to make it worth the extra cost of multinational production.

2. (10 pts.) Consider the model in which firms are heterogeneous in productivity. Firms in country one can serve two foreign countries by exporting or multinational production. The only difference between the two foreign countries is that one has a large GDP and one has a small GDP.

The model predicts that the smallest country-one exporter to the large-GDP country will be more productive than the smallest country-one exporter to the small-GDP country. (By smallest exporter, we mean the exporter with the smallest sales to the foreign country.)

FALSE. Since firm size is increasing with productivity, the smallest exporter to a country is the one with the lowest productivity. The large-GDP country can sustain less productive exporters because the operating profit earned by a firm is larger in larger countries. Thus the break-even productivity to export is smaller for the exporters to the large-GDP country.

3. (10 pts.) A country is a good candidate for export platform FDI if it is close to the parent firm, close to other markets, and has low production costs.

FALSE. Export platforms are far from the parent. If the parent was close to the export platform, the parent could export directly to the third countries.

4. (10 pts.) Deloitte Touche Tohmatsu Limited, a multinational management and tax consultancy, employs more than 240,000 professionals across the world. Deloitte's network of global offices, which provide on-site consulting to thousands of customers, is consistent with the proximity-concentration tradeoff.

TRUE. Consulting services can be costly to provide from abroad. It is expensive and difficult to continually move personnel across countries to provide services. The high cost of serving foreign markets (and the small returns to scale in office space) make consulting networks consistent with the proximity-concentration tradeoff.

5. Suppose the cost of operating a foreign affiliate is not only technological (costs associated with production) but also regulatory (costs imposed by the host-country government). These regulatory costs could be extra reporting burdens, permit/license fees, and having to recertify a company to operate abroad. In the model, let $f^p = f^T + f^R$ where f^T are the technological costs and f^R are the regulatory costs.

One of the goals of the Transatlantic Trade and Investment Partnership (T-TIP) is to reduce the regulatory costs associated with foreign direct investment. In this question, we will use the two-country, heterogenous firm model to study the impact of T-TIP on US firms that serve the United Kingdom.

Let $E_{uk} = 1000$, $\epsilon_{uk} = 4$, $w_{us} = 1.5$, $w_{uk} = 1.5$, $f^T = 3$, $f^R = 1$, $f^e = 1.25$, and $\tau = 0.2$.

- a. (5 pts.) What is the productivity level of the smallest US firm that exports to the UK? Call this level of productivity $\underline{\varphi}^e$.

$$\begin{aligned} \pi_{us}^e(\underline{\varphi}^e) &= \frac{E_{uk}}{\epsilon_{uk}} \left(\frac{\epsilon_{uk}}{\epsilon_{uk} - 1} \frac{1}{\underline{\varphi}^e} w_{us}(1 + \tau) \right)^{1 - \epsilon_{uk}} - w_{us} f^e = 0 \\ \frac{1000}{4} \left(\frac{4}{3} \frac{1}{\underline{\varphi}^e} 1.5 * 1.2 \right)^{-3} &- 1.5 * 1.25 = 0 \\ 18.084 (\underline{\varphi}^e)^3 &= 1.875 \\ \underline{\varphi}^e &= (1.875/18.084)^{1/3} = 0.4697 \end{aligned}$$

- b. (8 pts.) What is the productivity level, $\underline{\varphi}^m$, for which a firm in the US is indifferent between exporting to the UK and operating a foreign affiliate in the UK?

$\underline{\varphi}^m$ solves

$$\begin{aligned} \pi_1^e(\underline{\varphi}^m) &= \pi_1^m(\underline{\varphi}^m) \\ \frac{E_{uk}}{\epsilon_{uk}} \left(\frac{\epsilon_{uk}}{\epsilon_{uk} - 1} \frac{1}{\underline{\varphi}^m} w_{us}(1 + \tau) \right)^{1 - \epsilon_{uk}} - w_{us} f^e &= \frac{E_{uk}}{\epsilon_{uk}} \left(\frac{\epsilon_{uk}}{\epsilon_{uk} - 1} \frac{1}{\underline{\varphi}^m} w_{uk} \right)^{1 - \epsilon_{uk}} - w_{uk} f^p \\ \frac{1000}{4} \left(\frac{4}{3} \frac{1}{\underline{\varphi}^m} 1.5 * 1.2 \right)^{-3} - 1.5 * 1.25 &= \frac{1000}{4} \left(\frac{4}{3} \frac{1}{\underline{\varphi}^m} 1.5 \right)^{-3} - 1.5 * 4 \\ 18.084 (\underline{\varphi}^m)^3 &= 31.25 (\underline{\varphi}^m)^3 - 4.125 \\ \underline{\varphi}^m &= (-4.125/(18.084 - 31.25))^{1/3} = 0.6792 \end{aligned}$$

- c. (8 pts.) Suppose implementing T-TIP eliminates the regulatory costs of foreign production, $f^R = 0$, but everything else stays the same. What are the new values of $\underline{\varphi}^e$ and $\underline{\varphi}^m$?

$\underline{\varphi}^e$ does not change.

To find $\underline{\varphi}^m$

$$\frac{1000}{4} \left(\frac{4}{3} \frac{1}{\underline{\varphi}^m} 1.5 * 1.2 \right)^{-3} - 1.5 * 1.25 = \frac{1000}{4} \left(\frac{4}{3} \frac{1}{\underline{\varphi}^m} 1.5 \right)^{-3} - 1.5 * 3$$

$$18.084 (\underline{\varphi}^m)^3 = 31.25 (\underline{\varphi}^m)^3 - 2.625$$

$$\underline{\varphi}^m = (-2.625 / (18.084 - 31.25))^{1/3} = 0.584196$$

- d. (11 pts.) As a result of T-TIP, the influx of new investment into the UK has caused an increase in the demand for UK workers, driving up their wages, w_{uk} . Does the higher wage dampen or amplify the impact of T-TIP on FDI from the US into the UK? Explain your answer.

The increase in wages will dampen the effect of T-TIP.

If wages in the UK stayed constant, the decrease in $\underline{\varphi}^m$ found in part c. would be the correct break-even productivity. If wages increased in the UK, the break-even productivity would rise, so fewer firms would want to operate an affiliate in the UK compared to the case in which the UK wage stayed constant.

6. A firm in the United States would like to serve Germany and Hungary. It has narrowed down its choices to either operating a plant in Germany (a larger, higher-wage country) and using it to serve Germany and Hungary, or operating a plant in Hungary (a smaller, lower-wage country) and using it to serve Germany and Hungary. The US firm has productivity $\varphi = 2$, and the two economies can be described by $\epsilon_h = \epsilon_g = 3$, $f^p = 1.25$, $f^e = 0.75$, $\tau_{g,h} = 0.2$, $E_h = 100$, $E_g = 1000$, $w_h = 0.9$, $w_g = 1.0$.
- a. (4 pts.) Where will the US firm locate its plant? Show the calculations that support your answer.

If the export platform is in Germany,

$$\pi = \frac{E_g}{\epsilon_g} \left(\frac{\epsilon_g}{\epsilon_g - 1} \frac{w_g}{\varphi} \right)^{1-\epsilon_g} + \frac{E_h}{\epsilon_h} \left(\frac{\epsilon_h}{\epsilon_h - 1} \frac{w_g}{\varphi} (1 + \tau) \right)^{1-\epsilon_h} - w_g f^p - w_g f^e$$

$$\pi = \frac{1000}{3} \left(\frac{3}{2} \frac{1}{2} \right)^{-2} + \frac{100}{3} \left(\frac{3}{2} \frac{1}{2} (1.2) \right)^{-2} - 1 * 1.25 - 1 * 0.75 = 632.745$$

If the export platform is in Hungary,

$$\pi = \frac{E_g}{\epsilon_g} \left(\frac{\epsilon_g}{\epsilon_g - 1} \frac{w_h}{\varphi} (1 + \tau) \right)^{1-\epsilon_g} + \frac{E_h}{\epsilon_h} \left(\frac{\epsilon_h}{\epsilon_h - 1} \frac{w_h}{\varphi} \right)^{1-\epsilon_h} - w_h f^p - w_h f^e$$

$$\pi = \frac{1000}{3} \left(\frac{3}{2} \frac{0.9}{2} (1.2) \right)^{-2} + \frac{100}{3} \left(\frac{3}{2} \frac{0.9}{2} \right)^{-2} - 0.9 * 1.25 - 0.9 * 0.75 = 579.412$$

The firm should build an export platform in Germany.

- b. (8 pts.) Explain the economic intuition behind your choice of Germany or Hungary as an export platform.

Even though Hungary has lower production costs, the large market size in Germany dominates the profit calculation.

If the firm located in Hungary, it would save on marginal costs, but it would have to ship large quantities to Germany, which would be expensive.

If the firm located in Germany, it pays a larger marginal cost, but it sells most of its output to the local market in Germany. Since it does not sell much to Hungary, the export costs are small.

7. Our model of horizontal FDI is characterized by the parameters $w_1, w_2, E_1, E_2, \epsilon_1, \epsilon_2, f^p, f^e$, and τ .
- a. (8 pts.) From the perspective of a firm in country one, which parameter(s) are *most important* for generating a desire for proximity to country two?

The desire to be proximate to country two is driven largely by τ and E_2 . If τ is large (exporting is expensive) the firm wants to be near country two to save on these export costs and earn a larger market share. If E_2 is large, then the amount of exports will also be large, which also generates a desire to be close to country two and save on export costs.

- b. (8 pts.) From the perspective of a firm in country one, which parameter(s) are *most important* for generating a desire concentrate production?

The desire to concentrate production is largely governed by the size of the production cost, f^p . If the fixed production cost is small, then there is not a large penalty to spreading production out over many locations. If f_p is large, however, the firm would like to concentrate production in as few places as possible, to avoid paying f^p several times.
