Introduction
Historical selective removal of red spruce, along with a range of biotic and abiotic stressors, has significantly impacted the composition and structure of mixedwood stands in the transition zone between spruce-fir and northern hardwoods forests. This land-use legacy, in concurrence with the difficulty of regenerating shade-tolerant red spruce, has made managing mixedwoods in the northeastern US uniquely challenging. Key knowledge gaps regarding the spatiotemporal recruitment dynamics of these forests, particularly the red spruce component, limits our ability to develop effective silvicultural strategies for restoring this regionally important forest system.

Research Objectives
• Reconstruct spatiotemporal recruitment dynamics to identify critical recruitment limitations of red spruce
• Elucidate natural development pathways using reconstructed canopy disturbance histories
• Inform ecological silvicultural systems to restore and maintain these forests

Field Methods
• Nine 0.25-ha plots total established in old-growth mixedwood forests in New York (Figure 1) and New Hampshire (Figure 2)
• Plots in Township 40 were located in the west-central Adirondack Park, and plots in New Hampshire were in the Bowl Research Natural Area
• All stems ≥10 cm DBH were mapped and sampled for dendroecological reconstructions through extraction of increment cores

Age Structure
• Reconstructions of recruitment dynamics at Township 40 indicate consistent, decadal recruitment of red spruce over the past 3 centuries (Figure 3)
• The oldest spruce (6.1%) recruited into the stand from 1700–1730
• Over half of all living trees (57.5%) recruited into the stand from 1930–1970

Spatial Analysis
• Spatial patterns of tree locations were analyzed using pairwise correlation function of species for all stems, living and dead pooled (Figure 6)
• Spatially random arrangements of trees at all plots in Township 40
• Clustering observed within first 0.5 m at the lower elevation plot in The Bowl, but no significant clustering observed in the middle and high elevation plots
• Ongoing work will include analyzing spatial patterns of different age groups, and reconstructing the canopy disturbance histories at both sites

Acknowledgements
Thanks to Tony D’Amato and everyone in the Silviculture & Applied Forest Ecology Lab at UVM. Thanks to Colby Bosley-Smith, Tom Gasper, Maegan Aldous, and Luther Millison for their hard work in the field and lab. Thanks to Steve Langdon of the Shingle Shanty Preserve & Research Station for his guidance and support. Funding was provided by the USDA Forest Service Northern Research Station and UVM Rubenstein School of Environment and Natural Resources.

Table 1. Mean values of structural characteristics by site (SE = ± standard error). Live tree density, snag density, and basal area calculated for stems ≥10 cm DBH. Saplings classified as stems ≤10 cm DBH.
