SPINE IMAGING GUIDELINES
Effective 06-06-2016

Clinical Decision Support Tool
for Advanced Diagnostic Imaging

Common symptoms and symptom complexes are addressed by this tool. Imaging requests for patients with atypical symptoms or clinical presentations that are not specifically addressed will require physician review. Consultation with the referring physician may provide additional insight.

**SP-1.1 General Considerations**

- An initial clinical evaluation within 60 days is required before advanced diagnostic imaging can be considered and should include a relevant history and physical examination (including a detailed neurological examination), appropriate laboratory studies, non-advanced imaging modalities, results of manual motor testing, the specific dermatomal distribution of altered sensation, reflex examination, and nerve root tension signs (Lasegue’s Test). *The initial clinical evaluation must be face-to-face; other forms of contact (telephone call, electronic mail or messaging) are not acceptable as an initial evaluation.*

  - For those spinal conditions/disorders for which the Spine Imaging Guidelines require a plain x-ray of the spine prior to consideration of an advanced imaging study, the plain x-ray must be performed after the current episode of symptoms started or changed (See **SP-2.1**)

- Clinical re-evaluation: Failure of significant clinical improvement after a recent (within 3 months) six week trial of physician-directed treatment/observation and documentation of a relevant history and physical examination (including a detailed neurological examination). A clinical re-evaluation is required documenting:

  - Physician-directed treatment may include education, activity modification, NSAIDs (non-steroidal anti-inflammatory drugs), narcotic and non-narcotic analgesic medications, oral or injectable corticosteroids, a physician-directed home exercise/stretching program, cross-training, avoidance of aggravating activities, physical/occupational therapy, spinal manipulation, interventional pain procedures and other pain management techniques.

    - *Clinical re-evaluation must be face-to-face; other forms of contact (telephone call, electronic mail or messaging) are not acceptable as clinical re-evaluation.*

- Any bowel/bladder abnormalities or emergent or urgent indications should be documented at the time of the initial clinical evaluation and clinical re-evaluation.

- Motor deficits (weakness) should be defined by the specific myotomal distribution (for example, weakness of toe flexion/extension, knee flexion/extension, ankle dorsi/plantar flexion, wrist dorsi/palmar flexion) and gradation of muscle testing should be documented as follows:

<table>

<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
</tbody>
</table>

Effective 06-06-2016

Spine Page 4 of 35
Movement possible against gravity with full or normal resistance

- Altered sensation to pressure, pain, and temperature should be documented by the specific anatomic distribution (for example, dermatomal and stocking/glove).

- Pathological reflexes (e.g. positive Hoffmann’s, Babinski, Chaddock Sign), asymmetric reflexes and reflex examination should be documented as follows:

<table>
<thead>
<tr>
<th>Grading of Reflex Testing</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<tr>
<td>3+</td>
</tr>
<tr>
<td>4+</td>
</tr>
</tbody>
</table>

- Advanced diagnostic imaging may be indicated if serious underlying spinal and/or non-spinal disease is suggested by the presence of certain patient factors referred to as “red flags”. See: (SP-1.2 Red Flag Indications).

- Spinal specialist evaluation can be helpful in determining the need for advanced diagnostic imaging, especially for patients following spinal surgery.

- The need for repeat advanced diagnostic imaging should be carefully considered and may not be indicated if prior advanced diagnostic imaging has been performed. Requests for simultaneous, similar studies such as spinal MRI and CT need to be documented as required for preoperative surgical planning. These studies may be helpful in the evaluation of complex failed spinal fusion cases or needed for preoperative surgical planning when the determination of both soft tissue and bony anatomy is required.

- Serial advanced imaging, whether CT or MRI, for surveillance of healing or recovery from spinal disease is not supported by the currently available scientific evidence-based medicine for the majority of spinal disorders.

- Advanced imaging is generally unnecessary for resolved or improving spinal pain and/or radiculopathy.

- For patients experiencing chronic spine pain, advanced diagnostic imaging has not been shown to be of value in patients with stable, longstanding spinal pain without neurological features or without clinically significant or relevant changes in symptoms or physical examination findings.
SP-1.2 Red Flag Indications

*Red Flag Indications are intended to represent the potential for life or limb threatening conditions.* Red Flag Indications are clinical situations in which localized spine pain and associated neurological features are likely to reflect serious underlying spinal and/or non-spinal disease. Advanced diagnostic imaging of the symptomatic level is appropriate and/or work-up for a non-spinal source of spine pain for Red Flag Indications.

**Red Flag Indications** include:

<table>

SPINE IMAGING GUIDELINES

SP-2.1 Anatomic Guidelines

✓ Anatomic regions of the spine/pelvis that are included in the following MRI and CT advanced diagnostic imaging studies:
  o Cervical spine: from the skull base/foramen magnum through T1
  o Thoracic spine: from C7 through L1
  o Lumbar spine: from T12 through mid-sacrum
  o Pelvis: includes hips, sacroiliac joints, sacrum, coccyx

✓ CT or MRI of the cervical and thoracic spine will image the entire spinal cord since the end of the spinal cord or conus medullaris usually ends at L1 in adults. Therefore, lumbar spine imaging is not needed when the goal is to image only the spinal cord unless there is known or suspected low lying conus medullaris (e.g. tethered cord).

✓ Plain x-ray should be the initial evaluation for certain suspected spine conditions, including:
  o Pathological compression fractures (see SP-11)
  o Lumbar Spondylolysis/Spondylolisthesis (see SP-8)
  o Ankylosing Spondylitis (see SP-10)
  o Cervical, Thoracic, and Lumbar Trauma (see SP-3, SP-4, SP-6)
  o Scoliosis/Kyphosis and other spinal deformities (see SP-14)
  o Sacroiliac joint conditions (see SP-10)
  o Post-operative spinal disorders (see SP-15)

SP-2.2 MRI of the Spine

(See SP-1 Procedure Codes Associated with Spine Imaging)

✓ Spine MRI is the procedure of choice to evaluate disc disease, spinal cord and nerve root disorders and most other spinal conditions including evaluation of congenital anomalies of the spine and spinal cord.

✓ Spine MRI is performed either without contrast, with contrast or without and with contrast. A “with contrast” study alone is appropriate only to complete a study begun without contrast. Contrast is generally not indicated for most disc and nerve root disorders, fractures and degenerative disease.

✓ Indications for MRI with contrast or without and with contrast:
  o Suspicion for or surveillance of known spine/spinal canal/spinal cord neoplastic disease
  o Suspicion, diagnosis of or surveillance of spinal infections, multiple sclerosis or other causes of myelitis, syringomyelia, cauda equina syndrome or other “red flag” indications (See SP-1.2 Red Flag Indications).
Spinal imaging for patients having undergone recent spinal surgery e.g., laminectomy, discectomy, spinal decompression, when history and physical examination is suspicious for hematoma, post-surgical infection, or cerebrospinal fluid (CSF) leak (See **HD-13**).

**Positional MRI:**
- Positional MRI is also referred to as dynamic, weight-bearing or kinetic MRI. Currently, there is inadequate scientific evidence to support the medical necessity of this study. As such, it should be considered experimental or investigational. (See **HD-24.6**)

**SP-2.3 CT of the Spine**  
(See **SP-1 Procedure Codes Associated with Spine Imaging**)

**CT Spine:**
- Spine CT is useful for defining bony anatomy and detail.
- Spine CT indications include:
  - Individuals who cannot have MRI (with implanted ferromagnetic materials or electronically, magnetically or mechanically activated implanted devices that are not determined by the manufacturer as MRI compatible)
  - Any spinal trauma/fractures, especially spinal trauma/fractures that could result in spinal instability and spinal cord/spinal nerve compression
  - Spinal neoplastic disease – primary or metastatic
  - In conjunction with myelography or discography (See **SP-2.4** and **SP-2.5**)
  - To assess spinal fusions when pseudoarthrosis is suspected (not to be used for routine post-operative assessment where x-rays are sufficient and/or there are no concordant clinical signs or symptoms)
  - Congenital, developmental or acquired spinal deformity (see **SP-14~Scoliosis**)
  - Preoperative evaluation to define abnormal or variant spinal anatomy that could influence the placement of internal fixation devices such as pedicle screws
  - Spondylolysis when routine x-rays are negative and/or MRI is equivocal, indeterminate or non-diagnostic (See **SP-8 Spondylolysis/Spondylolisthesis**)

**SP-2.4 CT/Myelography**  
(See **SP-1 Procedure Codes Associated with Spine Imaging**)

**CT/Myelography:**
- CT/Myelography is generally unnecessary as an initial study when a diagnostic quality MRI has been obtained.
- CT/Myelography indications include:
  - To clarify equivocal, indeterminate or non-diagnostic MRI findings or to further evaluate the significance of multiple spinal abnormalities
When an MRI is contraindicated (See SP-2.2 MRI of the Spine)
- Preoperative planning for spine surgery, (e.g., multilevel spinal stenosis or when a previous MRI is insufficient, equivocal, indeterminate or non-diagnostic)
- Evaluation after previous spinal surgery when an MRI without and with contrast is contraindicated or MRI results are equivocal, indeterminate or non-diagnostic.
- To evaluate calcified lesions, (e.g., osteophytes, ossification of the posterior longitudinal ligament (OPLL))

**SP-2.5 Provocative Discography CT**

**Provocative Discography/CT:**

- This is a controversial procedure purported to diagnose (or rule-out) a discogenic “pain generator.” i.e., the source of non-specific axial spinal pain. This diagnostic study, when reported as positive, is often used as an indication for spinal fusion in patients with non-specific axial back pain.

- The following uses of discography are considered controversial:
  - To identify a symptomatic pseudoarthrosis in a failed spinal fusion
  - To identify which of two herniated discs seen on MRI is symptomatic when not determined clinically or otherwise
  - To confirm the discogenic nature of pain in a patient with an abnormal disc seen on MRI and to rule out pain from an adjacent disc level
  - To confirm the presumptive diagnosis of “internal disc disruption”
  - Discography of the cervical and/or thoracic spine

**SP-2.6 Ultrasound of the Spinal Canal**

- Spinal canal ultrasound (CPT®76800) describes the evaluation of the spinal cord (canal and contents) most often performed in newborns, infants, young children and intraoperatively.

- CPT®76800 describes evaluation of the entire spine and should not be reported multiple times for imaging of different areas of the spinal canal.

- CPT®76998, rather than CPT®76800, should be used to report intraoperative spinal canal ultrasound (ultrasonic guidance).

**Indications for spinal canal ultrasound (CPT®76800):**

- Generally, limited to infants, newborns and young children because of incomplete ossification of the vertebral segments surrounding the spinal cord, including the assessment of CSF in the spinal canal and for image-guided lumbar puncture.

- When ossification of the vertebral segments is incomplete for evaluation of suspected or known tethered cord

- Evaluation of suspected occult and non-occult spinal dysraphism
✓ Evaluation of spinal cord tumors, vascular malformations and cases of birth-related trauma
✓ Contraindicated for use in the adult spine for the assessment of spinal pain, radiculopathy, facet inflammation, nerve root inflammation, disc herniation, and soft tissue conditions surrounding the adult spine other than for superficial masses (See MS-10~Soft Tissue Mass and Lesion of Bone).

**SP-2.7 Limitations of Spinal Imaging in Degenerative Disorders**

✓ Non-specific axial spinal pain is ubiquitous. Advanced diagnostic imaging infrequently identifies the source of the spinal pain (pain generator).

✓ Incidental findings on MRI and CT, including bulging, protruding, extruding or herniated discs, are often non-concordant, asymptomatic and increase in incidence as the spine ages.

✓ In individuals with poorly defined clinical presentations, “abnormal” spinal advanced diagnostic imaging results are infrequently clinically concordant, significant, material or substantive and may even lead to inappropriate treatment.

✓ Performing advanced spinal imaging based only on the presence of spinal degenerative findings identified on x-rays is not generally indicated in patients who are either asymptomatic or present with non-specific axial spinal pain.

**SP-2.8 Miscellaneous Spinal Lesions**

**Vertebral body hemangiomas:**

✓ Vertebral body hemangiomas are common and are generally benign and incidental findings on plain x-rays and advanced diagnostic imaging studies.

✓ If the appearance of a hemangioma is typical on plain x-ray, further spinal advanced diagnostic imaging is not usually required, unless there are associated neurologic symptoms or signs on physical examination.

✓ Occasionally, MRI may be equivocal, indeterminate or non-diagnostic and CT without contrast of the spinal area is indicated to help clarify the diagnosis.

✓ No follow-up imaging is necessary once the diagnosis of a vertebral body hemangioma is established without neurological features.

**Tarlov cysts:**

✓ Tarlov cysts are most often cystic dilatations of nerve root sleeves in the lumbar spine and sacrum.

✓ Controversy exists as to whether Tarlov cysts can result in neurologic signs and symptoms but they can result in erosion of the adjacent bone.

✓ Usually Tarlov cysts are benign, incidental findings on advanced diagnostic imaging studies. Further evaluation of a known or suspected Tarlov cyst can be performed with
a MRI without and with contrast study (CPT®72158) or with Lumbar CT/Myelography (CPT®72132).

**Other spinal lesions:**
- MRI without and with contrast or a CT without contrast is appropriate if:
  - Other spinal lesions are seen on routine x-rays or a non-contrast MRI; **and**
  - These additional advanced imaging studies are recommended by a spine specialist or radiologist to further characterize or diagnose the lesion; **or**
  - Required for surgical planning
- Evaluation of CSF Leak: See **HD-11~Headache, Adult**

**SP-2.9.1 MRA Spinal Canal**
- Spine MRA imaging is utilized infrequently.
- Cerebrospinal Fluid (CSF) flow studies using MRI are included in the CPT® code set 70551-70553 and should not be coded or reported separately.

**Indications may include:**
- Suspected spinal cord arteriovenous malformation (AVM) or arteriovenous fistula (AVF):
  - Spine MRI of the relevant spine region without and with contrast should be the initial imaging study.
  - If suspicion for a spinal AVM or AVF is high based upon the results of the spine MRI, catheter angiography is recommended (CPT®72159 or CPT®70496).
- Subarachnoid hemorrhage where no brain aneurysm has been previously identified
  - Catheter angiography (CPT®70496) should be performed and is the most definitive study to define possible spinal pathology resulting in a spinal canal subarachnoid hemorrhage.
  - See: **HD-1.5 General Guidelines**
  - See: **HD 12.1 Intracranial Aneurysms and AVM**
- Preoperative planning
  - Spinal canal MRA may be useful in identifying major intercostal feeder vessels to the spinal cord prior to surgical procedures that might interfere with this blood supply to the spinal cord. However, catheter angiography (CPT®72159) is generally a more definitive study for this purpose.

**SP-2.9.2 Spine PET**
- At the present time there is controversy regarding spine PET due to inadequate scientific evidence to support the medical necessity of PET for the routine assessment of spinal disorders, other than for neoplastic disease
(See Oncology Imaging Guidelines)

✓ SPECT has been described to identify spinal pain generators, pseudoarthrosis of spinal fusion or hardware failure when conventional advanced diagnostic imaging studies are inconclusive, non-diagnostic or equivocal.

✓ Spine PET should be considered experimental or investigational.

References

### Neck (Cervical Spine) Pain without Neurological Features

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period

**Advanced Diagnostic Imaging:** MRI Cervical Spine, without contrast (CPT®72141)

**Comments:** CT Cervical Spine without contrast (CPT®72125) or CT Myelography (CPT®72126) is appropriate when MRI is contraindicated.

### Neck (Cervical Spine) Pain with Neurological Features

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period

**Advanced Diagnostic Imaging:** MRI Cervical Spine, without contrast (CPT®72141)

**Comments:** CT Cervical Spine without contrast (CPT®72125) or CT Myelography (CPT®72126) is appropriate when MRI is contraindicated.

### Neck (Cervical Spine) Trauma

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period
- Plain x-rays of cervical spine negative for fracture

**Advanced Diagnostic Imaging:** MRI Cervical Spine without contrast (CPT®72141) or CT Cervical Spine without contrast (CPT®72125)

**Comments:** A 6 week trial of physician-directed treatment and/or observation and clinical re-evaluation is *not* required for patients with a high risk mechanism of cervical spine injury within the last 3 months (See below**).

**High risk mechanisms of cervical spine injury may include:**
- Head trauma and/or maxillofacial trauma
- Pedestrian in a motor vehicle accident
- Fall from above standing height
- Diving accident
- Head-on motor vehicle collision without/with airbag deployment
- Rollover motor vehicle collision
- Ejection from the vehicle in a motor vehicle collision
- High speed of the vehicle at the time of collision
- Not wearing a seatbelt/shoulder harness in a motor vehicle collision
- Patients with ankylosing spondylitis are at high risk of cervical spine fractures even with minor direct/indirect trauma to the cervical spine which can result in quadriparesis/quadriplegia

✅ **Red Flag Indications:** See **SP-1.2 Red Flag Indications**

**Practice Notes:**

Pain radiation patterns from the cervical spine area into the thoracic spine area do not necessarily justify the addition of thoracic spine advanced diagnostic imaging.

Cervical radiculopathy is often confused with shoulder disorders, brachial plexopathy, peripheral nerve entrapment and/or motor/sensory neuropathies. Electrodiagnostic testing (EMGs/NCVs) is generally used to confirm, not establish, a diagnosis of peripheral nerve entrapment and/or a motor/sensory neuropathy based upon history and physical examination findings. Electrodiagnostic testing is often considered when advanced imaging of the spine does not reveal neurocompressive pathology and/or after 6 weeks of unimproved symptoms of extremity pain, weakness, numbness and/or tingling.

**SP-4~UPPER BACK (THORACIC SPINE) PAIN without/with NEUROLOGICAL FEATURES and TRAUMA**

### Upper Back (Thoracic Spine) Pain without Neurological Features

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period

**Advanced Diagnostic Imaging:**

<table>
<thead>
<tr>
<th></th>
<th>MRI Thoracic Spine without contrast (CPT®72146)</th>
</tr>
</thead>
</table>

**Comments:**

A CT Thoracic spine without contrast (CPT®72128) or CT Myelography (CPT®72129) is appropriate when MRI is contraindicated.

### Upper Back (Thoracic Spine) with Neurological Features

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period

**Advanced Diagnostic Imaging:**

<table>
<thead>
<tr>
<th></th>
<th>MRI Thoracic Spine without contrast (CPT®72146)</th>
</tr>
</thead>
</table>

**Comments:**

A CT Thoracic spine without contrast (CPT®72128) or CT Myelography (CPT®72129) is appropriate when MRI is contraindicated.

### Upper Back (Thoracic Spine) Trauma

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period
- Plain x-rays of thoracic spine negative for fracture

**Advanced Diagnostic Imaging:**

<table>
<thead>
<tr>
<th></th>
<th>MRI Thoracic Spine without contrast (CPT®72146) or CT Thoracic Spine without contrast (CPT®72128)</th>
</tr>
</thead>
</table>

**Red Flag Indications:** See **SP-1.2 Red Flag Indications**

Thoracic spine radiculopathy often presents with pain radiation from the thoracic spine around the rib cage following the sensory distribution of an intercostal nerve.
✓ Advanced diagnostic imaging is generally not appropriate in evaluation of axial low back pain with radiation toward the thoracic region unless there are documented clinical features indicating a thoracic spine disorder.

Reference
Low Back (Lumbar Spine) Pain without Neurological Features

All of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period

Advanced Diagnostic Imaging: MRI Lumbar Spine without contrast (CPT® 72148)

Comments: A CT lumbar spine without contrast (CPT® 72131) or CT Myelography (CPT® 72132) is appropriate when MRI is contraindicated

Coccydynia without Neurological Features

All of the following are required prior to advanced imaging:

- Initial clinical evaluation performed
- Failure of recent (within 3 months) 6-week trial of physician-directed treatment and/or observation
- Clinical re-evaluation (within last 60 days) after treatment period

Advanced Diagnostic Imaging: MRI pelvis without contrast (CPT® 72195)

Comments: A CT pelvis without contrast (CPT® 72192) when MRI is contraindicated

Red Flag Indications: See SP-1.2 Red Flag Indications

Practice Notes:

Coccydynia is often reported by patients as “tailbone” pain that is usually idiopathic or post-traumatic and generally follows a benign course.

SP-7.1 Myelopathy

Myelopathy is the development of abnormal spinal cord function with long tract signs usually secondary to spinal cord compression, but also inflammation (transverse myelitis, MS, etc.), neoplastic disease or spinal cord infarction.

Examination findings may include loss of manual dexterity, spastic legs and ataxia with hyperreflexia and upgoing toes (positive Babinski), Hoffman’s sign, sustained clonus, Lhermitte’s sign, crossed radial reflex, inverted radial reflex and finger escape sign. Sensory level and urinary incontinence/retention may be seen. Advanced imaging is generally appropriate in the initial evaluation of documented or reasonably suspected myelopathy.

✔ Cervical and thoracic spine MRI without contrast, or without and with contrast, is appropriate for:
  o Initial evaluation of reasonably suspected myelopathy
  o Suspected tethered cord
  o Post-traumatic syrinx with increased spinal pain or a worsening neurological symptoms
  o Sustained, prominent, and unexplained Lhermitte’s Sign (reproducible electric sensation that shoots down the entire spine and sometimes into the limbs with sudden neck flexion)
  o Unexplained Babinski’s sign (extension of the great toe with splaying of the other toes) after advanced imaging of the brain
  o Hoffman’s sign after advanced imaging of the brain has been performed.

✔ CT/Myelography scan can also be considered, especially for surgical planning.

SPINE IMAGING GUIDELINES

SP-8.1 Spondylolysis
✓ Lumbar spine CT without contrast (CPT®72131) or lumbar spine MRI without contrast (CPT®72148) is appropriate if one of the following:
  o Plain x-rays are negative, equivocal or indeterminate and clinical suspicion is high; or
  o Failure of 6 weeks immobilization with a spinal orthosis and physician-directed treatment with clinical re-evaluation; or
  o Pre-operative evaluation; or
  o Red Flag Indications (See SP-1.2 Red Flag Indications)

✓ Bony healing cannot be achieved non-surgically in an established well defined isthmic pars interarticularis defect whether it is developmental or the result of a pars interarticularis fracture non-union. Repeat advanced diagnostic imaging is not beneficial in this setting.

SP-8.2 Spondylolisthesis
✓ CT lumbar spine without contrast (CPT®72131) or MRI lumbar spine without contrast (CPT®72148) can be considered after plain x-ray for the following:
  o Failure of 6 week trial of physician-directed treatment and clinical re-evaluation (See SP-1.1); or
  o Preoperative evaluation; or
  o Red Flag Indications (See SP-1.2 Red Flag Indications)

Practice Notes
Stress reactions and stress fractures of the pars interarticularis are most common in athletes and others whose activities involve repetitive flexion/extension loading of the lumbar spine and may be acute or chronic and unilateral or bilateral. Pars interarticularis defects can be an incidental finding on plain x-rays and is frequently asymptomatic.

Spondylolisthesis is the forward (anterolisthesis) or backward (retrolisthesis, usually not clinically significant) displacement of one vertebra in relation to an adjacent vertebra, most commonly at L4-5 and L5-S1, although other levels of the spine may be involved. Spondylolisthesis is often an incidental finding on plain x-ray and is frequently asymptomatic.

SPINE IMAGING GUIDELINES

SPINE IMAGING GUIDELINES

SP-9-LUMBAR SPINAL STENOSIS

SP-9.1 Lumbar Spinal Stenosis

✓ MRI lumbar spine without contrast (CPT® 72148) or CT Lumbar Spine without contrast (CPT® 72131) is appropriate for those patients with clinical suspicion of lumbar spinal stenosis if:
  o Failure of 6 week trial of physician-directed treatment and clinical re-evaluation (See SP-1.1); or
  o Red Flag Indications (See: SP-1.2 Red Flag Indications); or
  o Severe symptoms of neurogenic claudication restricting normal activity or requiring the frequent use of narcotic analgesics

✓ A CT/Myelogram lumbar spine (CPT® 72132) may also be considered for patients who have failed 6-weeks of physician-directed treatment if requested by the operating surgeon for surgical planning, especially for multi-level lumbar spinal stenosis.

Practice Notes

Lumbar spinal stenosis refers to a decrease in the space available for the neural elements within the spinal canal that include spinal nerve roots and the cauda equina. It is usually a degenerative condition of the aging spine which can be asymptomatic or a common cause of buttock/low back and/or leg pain (neurogenic claudication) in this population. Neurogenic claudication is a common symptom of lumbar spinal stenosis that is aggravated by walking, especially down hills or stairs, with prolonged standing and is often relieved by sitting and bending forward. Neurogenic claudication should be differentiated from vascular claudication (leg/calf pain) that is often aggravated by walking and relieved fairly rapidly by stopping and rest. The differential diagnosis for lumbar spinal stenosis should include peripheral vascular disease, hip disorders and peripheral neuropathy.

1. ACR Appropriateness Criteria, Low Back Pain. Rev 2008 Guidelines. AAFP Evidence Grade: A
SP-10~SACRO-ILIAC (SI) JOINT PAIN, INFLAMMATORY SPONDYLITIS/SACROILIITIS and FIBROMYALGIA

SP-10.1 Sacro-Iliac (SI) Joint Pain/Sacroiliitis

✔ Pelvis CT without contrast (CPT®72192) or MRI pelvis without contrast (CPT®72195) is appropriate if:
  ○ Initial plain x-rays are equivocal or not diagnostic; and
  ○ Failure of 6 weeks of physician-directed treatment and clinical re-evaluation (See: SP-1.1); or
  ○ Any one of the following:
    • Fractures of the sacrum or sacroiliac joint(s); or
    • Suspicion of neoplastic, inflammatory or infectious disease (See: SP-1.2 Red Flag Indications); or
    • Pre-operative planning

✔ See also: MS-15.1 Rheumatoid Arthritis and Inflammatory Arthritis

SP-10.2 Inflammatory Spondylitis

✔ Initial plain x-rays are equivocal or not diagnostic
  ○ MRI without contrast of the affected spinal region
  ○ MRI Cervical Spine without contrast (CPT®-72141) if a patient with documented ankylosing spondylitis reports neck pain following any head/maxillofacial/neck injury

SP-10.3 Fibromyalgia

✔ Advanced diagnostic imaging is not supported by the scientific evidence for the evaluation and treatment of fibromyalgia.

Practice Notes

Sacroiliitis can present with pain localized to the SI joint or referred pain to the buttock and/or posterior thigh without neurologic signs or symptoms. Affected individuals can often point to the SI joint as the pain source. Provocative and/or therapeutic SI joint anesthetic/corticosteroid injections can have diagnostic value.

There is no evidence demonstrating that advanced diagnostic imaging substantiates changes to patient management decisions in patients with proven SI joint disorders when visible on routine plain x-rays.
There is no evidence demonstrating that advanced diagnostic imaging substantiates changes to patient management decisions in patients with proven SI joint disorders when visible on routine plain x-rays.

MRI has shown inflammatory changes in the SI joints prior to visible x-ray changes in several studies. However, the ability of MRI to characterize inflammation in early ankylosing spondylitis, the ability of MRI to predict erosive changes, and the value of monitoring treatment effects using serial MRI studies remains controversial and investigational in adults.

1. *Rheumatology* 2004;43:234-237 Prospective Non-Randomized Study with Findings. AAFP Evidence Grade: B
SP-11.1 Pathological Spinal Compression Fractures

✓ MRI without contrast or CT without contrast of the affected spinal region can be considered after plain x-ray evaluation and the location of the patient’s spinal pain is concordant with the spinal x-rays for any one of the following:
  o X-rays reveal a new spinal compression fracture; or
  o X-rays are non-diagnostic and severe spinal pain persists for more than one week in a patient already predisposed to low energy/insufficiency fractures; or
  o The acuity of the spinal compression fracture deformity on plain x-ray is indeterminate. or
  o Surgical planning following known insufficiency spinal compression fractures in individuals who are candidates for kyphoplasty, vertebroplasty or other spine surgical procedures; or
  o Red Flag Indications (See: SP-1.2 Red Flag Indications)

Practice Notes

Insufficiency/low energy spinal compression fractures of the spine occur due to the lack of structural integrity to withstand physiologic loads and minor spinal trauma. Low bone mineral density is the primary etiology for most of these fractures but could also occur in the setting of other bone disease and medical conditions, in addition to neoplastic disease and infection. Sudden localized back pain, with or without trauma, is a typical presentation of insufficiency/low energy spinal compression fractures and can often be an incidental finding on plain x-rays and can be asymptomatic.

SPINE IMAGING GUIDELINES

SP-13~SPINAL CANAL/CORD DISORDERS (e.g. SYRINGOMYELIA)

SP-13.1 Initial Imaging Pathway

✓ MRI cervical spine without and with contrast (CPT®72156) is appropriate when syringomyelia is suspected

✓ Once a syrinx is identified by the initial MRI cervical spine without and with contrast and:
  o MRI of the brain, usually without contrast (CPT®70551) to evaluate for syringobulbia; and
  o MRI of the thoracic spine without contrast (CPT®72146) to define the lower most extent of the syrinx or to identify a skip lesion
  o Advanced diagnostic imaging of the lumbar spine is generally not indicated unless tethered cord is suspected.

SP-13.2 Follow-up Imaging:

✓ Annual MRI cervical spine without contrast (CPT®72141) and MRI without contrast of the brain and/or thoracic spine when involved

✓ Following surgical treatment (including posterior fossa decompression)

✓ Until non-progression of the syringomyelia is established

✓ Advanced diagnostic imaging every three years for life can be performed once non-progression of the syringomyelia is established

✓ Repeat advanced diagnostic imaging is appropriate when evidence of neurologic deterioration.

✓ Repeat advanced diagnostic imaging in spinal cord injury patients with post-traumatic syrinx is not appropriate without evidence of neurological deterioration.

Practice Notes

Syringomyelia may begin to form in childhood but rarely becomes symptomatic before the adult years.

References

SP-14.1 Spinal Deformities (e.g. Scoliosis/Kyphosis)

- MRI of the affected spinal regions is appropriate after plain x-rays (e.g. Cobb radiographs) of the affected spinal regions:
  - For preoperative evaluation; or
  - For cases of congenital scoliosis and other atypical curves that may be associated with spinal canal/cord pathology such as tethered cord, syringomyelia, diastematomyelia, or tumors; or
  - For cases of scoliosis when there are associated neurologic signs and symptoms on physical examination; or
  - Scoliosis with a convex left thoracic curve due to a high association of a convex left thoracic curve with underlying spinal canal/cord pathology

Practice Notes

Scoliosis is defined as a curvature of the spine in the coronal plane. Scoliosis can involve any or all levels of the spine but generally involves the thoracic and/or lumbar spine. Scoliosis initially occurs in the pediatric and adolescent population and persists throughout life. If scoliosis begins in adulthood, it is usually secondary to neurologic disorders (e.g., posttraumatic paralysis) or degenerative spondylosis. Sagittal plane spinal deformity (e.g. kyphosis, hyperlordosis) may be associated with scoliosis.

SPINE IMAGING GUIDELINES

SP-15~POST-OPERATIVE SPINAL DISORDERS

Following plain x-rays of the affected spinal regions post-surgical, (see SP-2.1 Anatomic Guidelines)

SP-15.1 Greater than Six Months Post-Operative

✓ MRI without and with contrast of the affected spinal region(s) is appropriate when:
  o Patient is more than six months post-operative; and
  o No significant improvement after a recent (within 3 months) six week trial of physician- directed treatment and/or observation with clinical re-evaluation
  o Red Flag Indications (See: SP-1.2 Red Flag Indications)

SP-15.2 Routine Post-Fusion Imaging

✓ Following a clinically successful spinal fusion, advanced diagnostic imaging is generally not indicated.

✓ PET is not currently indicated for the routine assessment of spinal fusions or unsuccessful spine surgery (See: SP-2.8).

SP-15.3 Prolonged Intractable Pain Following Spinal Surgery

Open discectomy and laminectomy:
  o MRI without and with contrast of the affected spinal region(s) if there are residual, new or recurrent symptoms related to the surgical site
    • CT/Myelography of the affected spinal region(s) if MRI is contraindicated

Spinal fusions with or without Open Discectomy and/or Laminectomy:
  o These can be challenging problems that may require more than one advanced imaging study.

SP-15.4 Revision Fusion Surgery

If requested by the operating surgeon, the following studies can be performed for pre-operative planning prior to surgical revision of a lumbar anterior spinal arthrodesis.
  o CTA pelvis (CPT®72191) and/or CTA abdomen (CPT®74175); or
  o MRA pelvis (CPT®72198) and/or MRA abdomen (CPT®74185)

References
SPINE IMAGING GUIDELINES

SP-16~OTHER IMAGING STUDIES and PROCEDURES RELATED to the SPINE IMAGING GUIDELINES

Positional, Kinetic, Dynamic or Weight-bearing MRI, see: SP-2.2 MRI of the Spine

For PET see: SP-2.8 Spine PET

For CT/Myelography see: SP-2.3 CT of the Spine

SP-16.1 MRA and CTA

✓ MRA and CTA are generally not indicated for pre-operative planning of initial anterior spinal surgery unless abnormal vasculature is known or reasonably anticipated.

SP-16.2 Epidural Steroid Injections

✓ Advanced diagnostic imaging studies of the spine are not required prior to spinal injection procedures unless the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines

SP-16.3 Advanced Imaging for Spinal Cord Stimulators (SCS)

✓ MRI thoracic spine without contrast (CPT®72146) is generally the study of choice. CT thoracic spine without contrast (CPT®72128) or CT/Myelography thoracic spine (CPT®72129) are acceptable alternatives.

✓ Imaging of the lumbar spine is not indicated for insertion of spinal cord stimulators

Practice Note

MRI has not been shown to change the outcome of interventional pain procedures in recent scientific evidence-based studies and without substantial change in the clinical picture or intervening surgery. Repeat advanced diagnostic imaging studies are not necessary with each spinal injection or series of spinal injections.
