Suicide Facts & Figures: United States 2021

Research suggests suicide is a leading cause of maternal death in the
1st year following childbirth.1

Maternal suicide is most frequently completed between 6 to 12 months postpartum.2

The severity and rapidly evolving nature of postpartum psychoses increases the risk of expulsion suicides.3

Depression during pregnancy greatly increases thoughts about suicide while pregnant.4

Suicide accounts for up to 20% of postpartum deaths.5

Suicide prevention, education and research will help prevent the untold deaths of thousands of women each year.
What We Will Cover

Overview of maternal suicide research and data collection in the U.S.

The role of Maternal Mortality Review Committees (MMRCs)

Maternal suicidal ideation, suicide risk factors, and racial disparities

Fireside Chat
Meet Dr. Goldman-Mellor

Sidra Goldman-Mellor, PhD, MPH
Associate Professor of Public Health
School of Social Sciences, Humanities, and Arts
University of California, Merced
Context

• Pregnant and birthing persons in U.S. die at a higher rate than in other high-income countries*

• Reducing these deaths is a public health and clinical priority

• Evidence suggests that suicide is a prevalent and increasing cause of death during pregnancy and the first year postpartum**

• This devastating outcome receives far less attention

*World Health Organization, 2019
**Metz et al. 2016, Wallace et al. 2016, Mangla et al. 2019
Key Terminology

- Maternal mortality
  - Death of a woman while pregnant or within 42 days of end of pregnancy, from any cause related to or aggravated by the pregnancy or its management (e.g., hemorrhage, hypertension, & venous thromboembolism)
  - Does not include “accidental or incidental” causes, such as suicide

- Pregnancy-related death (PRD)
  - Death of a woman while pregnant or within one year of the end of a pregnancy from any cause related to or aggravated by the pregnancy or its management
  - Does not include suicide
Key Terminology, Continued

• Pregnancy-associated death (PAD)
  – Death of a woman while pregnant or within one year of the end of a pregnancy from any cause
  – Includes suicide

• Maternal morbidity
  – “Morbidity” generally refers to any non-fatal illness and injury
  – Severe maternal morbidity (SMM): Unexpected outcomes of labor and delivery that result in significant short- or long-term consequences to a woman’s health (myocardial infarction, renal failure, eclampsia, sepsis, etc.)
  – Does not usually include mental health
Updated National Estimates Are Needed

- Most recent U.S. estimates of suicide rates during pregnancy & postpartum are from 2010
  - Health of reproductive-aged women has changed since then -- including rising rates of suicide
  - 2010-2020 also saw fertility declines
  - Need to understand trends for better prevention
- Recent collaborative work* examines pregnancy-associated death due to suicide (and other PADs) in U.S. from 2010-2019
  - Examined racial/ethnic disparities
  - Identified timing of deaths in relation to pregnancy

*Margerison, Roberts, Gemmill & Goldman-Mellor, under review
What do our Best Estimates Show?

- Used birth and death certificate data from 2010-2019 (from 33 states + DC that were using death certificates with pregnancy "checkbox")
- There were 11,782 total pregnancy-associated deaths from 2010-2019
- Of these, 558 deaths were suicides (5.4%) -- overall PAD ratio of 2.2 per 100,000 live births
  - 59.3% died due to maternal/obstetric causes
  - 10.7% due to drug-related causes
  - 5.4% due to homicide
  - 19.2% due to other causes
- PAD due to suicide fluctuated a bit, but increased approximately 32% from 2010-2019
Pregnancy Associated Deaths by Timing of Death

- Obstetric: 36% Pregnant at time of death, 35% Not pregnant at time of death, but pregnant within 42 days of death, 26% Pregnant 43 days to 1 year prior to death, 3% Pregnant within 1 year of death, exact timing unknown
- Homicide: 57% Pregnant at time of death, 8% Not pregnant at time of death, but pregnant within 42 days of death, 35% Pregnant 43 days to 1 year prior to death
- Suicide: 36% Pregnant at time of death, 13% Not pregnant at time of death, but pregnant within 42 days of death, 51% Pregnant 43 days to 1 year prior to death
- Drug-related: 34% Pregnant at time of death, 19% Not pregnant at time of death, but pregnant within 42 days of death, 47% Pregnant 43 days to 1 year prior to death

*Margerison, Roberts, Gemmill & Goldman-Mellor, under review*
Racial & Ethnic Disparities in Pregnancy-Associated Suicide Deaths

Suicide deaths per 100,000 live births

- Non-Hispanic White: 2.8
- NH Black: 1.6
- Hispanic: 1.3
- NH American Indian/Alaska Native: 7.7
- NH Asian/Pacific Islander: 2.0

Margerison, Roberts, Gemmill, & Goldman-Mellor. under review
Accounting for Under-reporting of Suicide Deaths

• Also attempted to quantify under-reporting of suicide death using previously published procedures**
  – Due to under-utilization of the pregnancy checkbox on the death certificate, as many as 50% of pregnancy-associated suicide deaths may be missed.

• After statistically accounting for (estimated) misclassified suicide deaths, the pregnancy-associated suicide death ratio changed from 2.2 to 5.1 per 100,000

• An estimated total of 844 suicide deaths were under-counted during our study period

• If we add those “missing” suicide deaths, suicide would account for 9.4% of all pregnancy-associated deaths

---

*Margerison, Roberts, Gemmill & Goldman-Mellor, under review
What Do We Conclude From These Findings?

- Suicide among pregnant and postpartum women is increasing, and accounts for a non-negligible proportion of pregnancy-associated deaths
- Most (64%) of these suicide deaths occur postpartum, the vast majority after the 6-week check-up
- Unacceptable racial/ethnic disparities in PAD suicide death, with American Indian/Alaska Native women at far greater risk
  - Nearly 3x higher than NH White women, who themselves are relatively high-risk
- The contribution of suicide (and drug-related deaths & homicide) to overall pregnancy and postpartum mortality is likely much higher than unadjusted estimates would suggest
Meet Dr. Smid

Pregnancy-Associated Death
A death during or within one year of pregnancy, regardless of the cause. These deaths make up the universe of maternal mortality; within that universe are pregnancy-related deaths and pregnancy-associated, but not related deaths.

Pregnancy-Related Death
A death during or within one year of pregnancy, from a pregnancy complication, a chain of events initiated by pregnancy, or the aggravation of an unrelated condition by the physiologic effects of pregnancy.

Pregnancy-Associated, but Not Related Death
A death during or within one year of pregnancy, from a cause that is not related to pregnancy.

Pregnancy-Related Mortality Ratio
The number of pregnancy-related deaths (using the above definition) per 100,000 live births.

Ultimate question:
If the person who died had not been pregnant, would they have died?

• Currently in Round 3
Meet Dr. Zivin

Kara Zivin, PhD, MS, MA, MFA

Professor of Psychiatry, Obstetrics and Gynecology, Health Management and Policy/Public Health, University of Michigan
Faculty Associate, Survey Research Center, Institute for Social Research
Research Career Scientist, Center for Clinical Management Research (CCMR), VA Ann Arbor Healthcare System
Trends in Suicidal Ideation and Self-Harm Among Privately Insured Delivering Women

Suicide deaths are a leading cause of maternal mortality in the United States.

CDC maternal mortality statistics exclude suicide deaths.

Suicidal ideation or self-harm (suicidality) are often excluded from maternal morbidity measures.

Prevalence and trends in suicidality among childbearing individuals remain poorly described.

Research objective and study design

We sought to identify trends in suicidal ideation and intentional self-harm (suicidality) in a large, national cohort of commercially insured childbearing individuals

2006-2017 Optum™ Clinformatics™ Data Mart

Medical claims for a large, national, commercially insured population across all 50 states

Maternal Behavioral Health Policy Evaluation (MAPLE) study* cohort (N=595,237)

Individuals aged 15-44 continuously enrolled in a single commercial health insurance plan for one year before and one year after childbirth

Identification of suicidality in the year before or after childbirth based on ICD9-10 diagnosis codes during at least one inpatient or two outpatient visits

* R01 MH120124
Prevalence of suicidal ideation and self-harm among privately insured childbearing individuals 2006-2017
Prevalence of suicidal ideation and self-harm among privately insured childbearing individuals 2006-2017

Larger escalations among:
• Non-Hispanic Black
• Low income (≤400 federal poverty level)
• Younger (15-18 years old): prevalence of suicidality increased from 1.6% to 9.5% among individuals aged 15-18 years old
• Experiencing co-morbid anxiety and depression or serious mental illness

Among those with diagnoses of suicidality
• 45.1% took place in the pre-delivery period
• 58.7% took place in the post-delivery period
• These results include 3.8% with suicidality in both periods

Perinatal behavioral health diagnoses per 100 individuals
• Depression or anxiety: 2006=1.2%; 2017=2.6%
• Bipolar disorder: 2006=6.9%; 2017=16.9%
• Psychotic disorder: 2006=17.4%; 2017=46.2%
Conclusions, relevance, and next steps

The prevalence of suicidal ideation and self-harm occurring in the year preceding birth increased substantially over a 12-year period.

Younger, non-Hispanic Black, and those diagnosed with a behavioral health disorder had higher risks.

Policymakers, health plans, and clinicians should ensure access to universal suicidality screening and appropriate treatment for pregnant and postpartum individuals.

Future work should include individuals covered under Medicaid health insurance, as well as address disparities in detection, diagnosis, and treatment of suicidality in those with perinatal mental health conditions.
