INTRODUCTION

Background: Thioureidobutyronitrile, Kevetrin, induced apoptosis in wild type p53, mutant p53 and p53 null cell lines (*Shapiro 2013*). In A549 lung carcinoma cells, wild type p53 was stabilized by Kevetrin. Kevetrin induced non-genotoxic activation of the p53 signaling pathway (*Kumar 2012*). Kevetrin also induced p21 and PUMA, known transcriptional targets of p53 (*Kumar 2011*). Kevetrin caused accumulation of monoubiquitinated p53 and induced transcriptional independent apoptosis. In p53 mutant breast carcinoma cells (MDA-MB-231), Kevetrin induced degradation of hyperstable oncogenic mutant p53 and induced apoptotic cell death (*Kumar 2011*). Apoptotic cell death was also induced in K-562, a p53 null CML cell line. Consistent with *in vitro* data, Kevetrin showed potent antitumor activity in wild type p53 (A549), mutant p53 (MDA-MB-231), and p53 null (K-562) human tumor xenograft models (*Chafai-Fadela 2010*). Kevetrin has the unique ability to target both wild type and mutant p53 tumors controlling tumor growth in various preclinical tumor models (*Kumar 2012, Shapiro 2013*).

Based on the pre-clinical data, a Phase I study was initiated with Kevetrin for solid carcinomas at Dana-Farber/Harvard Cancer Center in 2012. Participating sites include Dana Farber Cancer Institute and Beth Israel Deaconess Medical Center.

Methods: Adults with refractory locally advanced or metastatic solid tumors, acceptable liver, kidney function, and hematologic status were eligible. Objectives include determination of DLT, MTD, pharmacokinetics, pharmacodynamics, and evaluating preliminary evidence of antitumor activity.

Kevetrin is given as an intravenous infusion once weekly for 3 weeks in a 28-day cycle. The starting dose was 10 mg/m². In a 3+3 design, groups of 3-6 subjects are evaluated for toxicity at each dose level. Dose escalation is based upon the number and intensity of adverse events in cycle 1. Kevetrin PK is characterized for the first and last doses given in cycle 1.

Kevetrin induced increases in p21 levels in lymphocytes in nonclinical studies (*Kumar 2011*); therefore p21 expression in peripheral blood mononuclear cells is measured as a pharmacodynamic biomarker. Antitumor activity by RECIST 1.1 criteria and serum tumor markers are assessed. The p53 status of tumors of selected subjects is determined.

Phase 1 study CTIX-0000

Dana-Farber/Harvard Cancer Center

ClinicalTrials.gov Identifier: NCT01664000

Sites:

- Dana-Farber Cancer Institute
- Beth Israel Deaconess Medical Center

Objectives:

- Evaluate the safety, tolerability, maximum tolerated dose (MTD)
- Determine recommended Phase 2 dose
- Characterize pharmacokinetic (PK) profiles
- Evaluate preliminary evidence of antitumor activity
- Explore potential biomarkers of tumor response

Study Design:

- Intravenous infusion once weekly for 3 weeks in a 28-day cycle
- Starting dose was 10 mg/m²
- Dose escalation in a 3+3 design, groups of 3-6 subjects are evaluated for toxicity at each dose level
- Dose escalation is based upon the number and intensity of adverse events in Cycle 1
- Once the MTD is established, up to 12 additional subjects may be enrolled at the MTD dose level
- PK is characterized for the first and last doses given in Cycle 1
- Antitumor activity by RECIST 1.1 criteria and serum tumor markers is assessed
- p53 status of tumors of selected subjects will be determined
- The total number of subjects planned is 60

Pharmacodynamic Biomarker:

- p21 expression in peripheral blood mononuclear cells

Key Eligibility Criteria:

- Adults with refractory locally advanced or metastatic solid tumors
- Acceptable liver and kidney function, and hematological status

Phase 1 study CTIX-0000

STATUS:

The Phase 1 trial began November 7, 2012

A total of 40 subjects have been enrolled to date, 34 have completed

Completed: Cohort 0 (10 mg/m²) through Cohort 9 (450 mg/m²)

Cohort 10: 750 mg/m² is ongoing

1 DLT occurred to date

The MTD has not yet been reached

SUBJECTS:

Average age: 63 ± 9 years

Age range: 42 to 85 years

Females / Males: 26 / 14

Cancer types of participating subjects

- 17 gynecological cancers
- 6 head & neck cancers
- 5 lung cancers
- 4 renal /urothelial / bladder cancers
- 3 skin cancers
- 2 prostate cancers
- 2 pancreatic / biliary cancers
- 1 liposarcoma

Cohort	Dose (mg/m ²)	Subject	Age	Sex	Cancer Type
9	450	132	74	female	ovarian
4	75	114	66	female	ovarian
3	50	111	59	female	ovarian
8	350	126	57	female	ovarian
0	10	103	79	female	ovarian stromal
8	350	206	58	female	metastatic ovarian
1	20	104	73	female	metastatic ovarian
8	350	124	59	female	papillary serous ovarian
8	350	125	57	female	endometrial
8	350	130	65	female	endometrial
8	350	131	66	female	endometrial
7	215	123	61	female	endometrial
1	20	106	71	female	metastatic endometrial
4	75	115	47	female	cervical
5	110	116	61	female	metastatic cervical
5	110	117	76	female	cervical mesonephric tumor
8	350	127	63	female	metastatic mullerian serous adeno
9	450	207	69	female	SCLC
1	20	201	69	female	SCLC
7	215	122	67	male	NSCLC
6	165	204	73	male	NSCLC
10	750	208	63	male	metastatic pulmonary basal cell
0	10	102	53	male	metastatic squamous cell carcinoma of the head and neck
9	450	133	54	male	laryngeal adenoid cystic
6	165	119	42	male	parotid myoepithelial
5	110	118	58	male	parotid
6	165	120	54	female	metastatic adenoid cystic ca of trachea
8	350	129	48	male	thymoma
3	50	110	62	female	metastatic renal cell carcinoma
3	50	203	52	female	urothelial
3	50	112	68	male	urothelial
2	30	108	62	male	metastatic bladder
4	75	113	59	male	prostate
2	30	107	56	male	prostate
7	215	121	85	male	atypical intradermal spindle cell neoplasm of scalp
1	20	105	75	female	metastatic melanoma
0	10	101	45	female	metastatic squamous cell carcinoma of the skin
2	30	202	69	female	metastatic pancreatic
7	215	205	63	male	cholangiocarcinoma
3	50	109	62	female	metastatic liposarcoma

Biomarker

Kevetrin induces cell cycle arrest and apoptosis through activation and stabilization of wild type p53, resulting in increased expression of target genes p21 and PUMA (*Kumar 2011*).

In a preclinical mouse model, Kevetrin induced p21 in lymphocytes (*Kumar 2011*); therefore p21 expression in peripheral blood mononuclear cells is measured at 7 and 24 hours after initiation of dosing as a pharmacodynamic biomarker in this trial.

Of 40 subjects enrolled to date, 31 were evaluable for changes in p21 biomarker (pre-dose and at least 1 time point post-dose blood sample obtained after first dose of Kevetrin).

Of the 31 evaluable subjects :

68 % had an increase in p21 expression in a range of 3% to 205%

48 % had an increase in p21 expression of ≥ 10%

These results suggest that Kevetrin activates p53 by inducing p21 gene expression.

SUMMARY

The Phase 1 study with Kevetrin, CTIX-0000, is in progress at Dana-Farber/Harvard Cancer Center in subjects with various solid carcinomas; the majority of which are gynecological cancers.

10 cohorts of subjects have been completed; the 11th cohort is ongoing. Only 1 DLT has been observed to date, but the MTD has not yet been reached. The current dose is 750 mg/m², 75-fold greater than the starting dose.

Kevetrin was shown to activate wild type p53 and degrade mutant p53. Since Kevetrin activates both transcriptional-dependent and transcriptional-independent pathways to promote apoptosis through wild type p53 activation and degrades oncogenic mutant p53, Kevetrin can function as a major inducer of apoptosis in many types of tumors independent of p53 mutation status.

In this Phase 1 study, the biomarker, p21 expression levels in peripheral blood, were increased in 68% of subjects and 48% had an increase in p21 expression at a level of ≥10%. These results suggest that Kevetrin activates p53 by inducing p21 gene expression.
