

AVZ Minerals
Limited

30 June 2017

Independent Review Confirms World Class Potential of the Manono Lithium Project

Highlights – Manono Lithium Project

- Assay results of samples collected from reconnaissance trenches confirm the presence of lithium mineralisation in pegmatites extending along strike for more than 13 kilometres.
- Assay results from trenching only include intervals of 29m @ 1.54% Li₂O and 38m @ 1.29% Li₂O in relatively unweathered pegmatite and 197m at 0.50% Li₂O in predominantly weathered pegmatite. Further results are awaited.
- Initial diamond core drilling of 1,734m is now complete, sampling of core is ongoing with assay results expected early August.
- Within the 13,000m zone there are six separate large pegmatites defined to date with lengths from 400m to 5,400m.
- It is confirmed that the six large pegmatites all contain spodumene, with spodumene mineralisation constituting up to 30% of the rock volume
- Logging of drill core completed to date indicates true thicknesses of the large pegmatites range from 50 to 220 metres – much larger than initially predicted.
- The next phase drilling program is planned with a view to having an initial lithium resource calculated by early 2018.

AVZ Minerals Limited (**AVZ or Company**) recently commenced exploration at the Manono Lithium Project. Independent Competent Person* (**CP**), Mr Peter Spitalny, has completed an initial technical review of the Manono Lithium Project at the request of the Company. The initial focus of the review has been upon surface sampling and mapping.

Mr Spitalny noted, “*The technical work observed so far has been to a high standard and with further procedural aspects now fully in place, one can be confident that all drilling and sampling will be to the highest quality to allow resources to be calculated during 2017 on what is perceived to be potentially a world class lithium deposit.*”

“The main characteristic of note with regard to the Manono pegmatites is that they are immense. Outcrops and exposures in pits suggest that the two largest pegmatites are the Carriere de L'est Pegmatite and the Roche Dure Pegmatite, both of which alone are of similar size or larger than the famous Greenbushes Pegmatite in Western Australia.”

AVZ Executive Chairman, Mr Klaus Eckhof commented “*The first visit of the CP has provided the necessary check and balance of work completed so far and more importantly further confirmation that AVZ’s Manono Lithium project is shaping up to be of a world class stature. The Company looks forward to continuing its drilling campaign and will shortly be seeking tenders for a significant drilling contract on the back of which JORC resources will be determined.*”

Mapping

The Manono Project contains two large areas of pegmatite, with the northeast area referred to as the Manono sector and the southwest area referred to as the Kitotolo sector. Mapping within the two sectors has established that there are many pegmatites, representing separate intrusions. For clarity in discussion of the main pegmatites, AVZ has named the six largest pegmatites using the names of the historical open-cut mines (shallow but extensive pits) within the area (Figure 1).

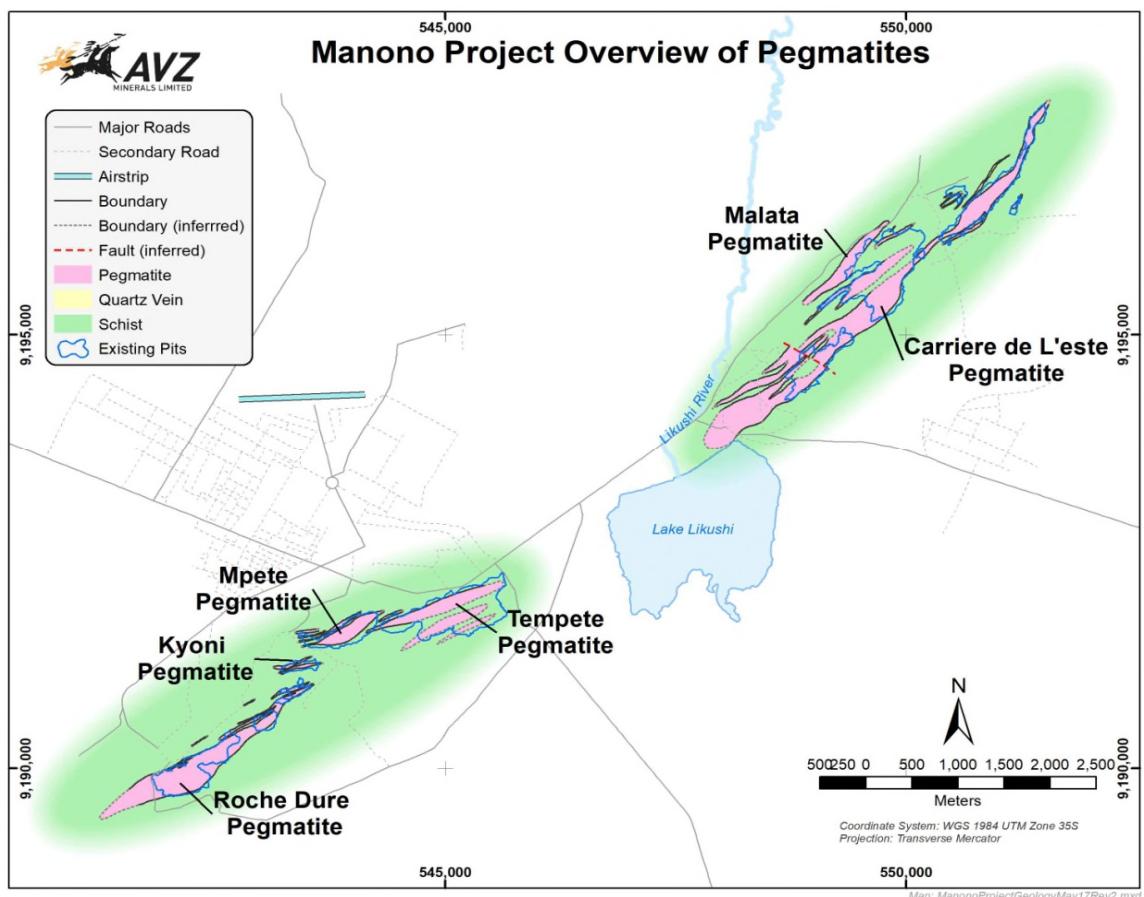

Figure 1: Manono Project Pegmatites

Observations of outcrops suggest that the main Li mineral in the large pegmatites is spodumene. The Malata Pegmatite contains, in addition to spodumene, some lepidolite. There is at least one small pegmatite exposed in the Kahungwe West pit (northern end of Manono sector) that is a lepidolite pegmatite.

It is noted that outcrops and exposures in pits suggest that the two largest pegmatites are the Carriere de L'est Pegmatite and the Roche Dure Pegmatite. Each of these alone is evidently as large or larger (Figure 2) than the famous Greenbushes Pegmatite in Western Australia where current resources are stated as 120Mt of 2.4% Li₂O.

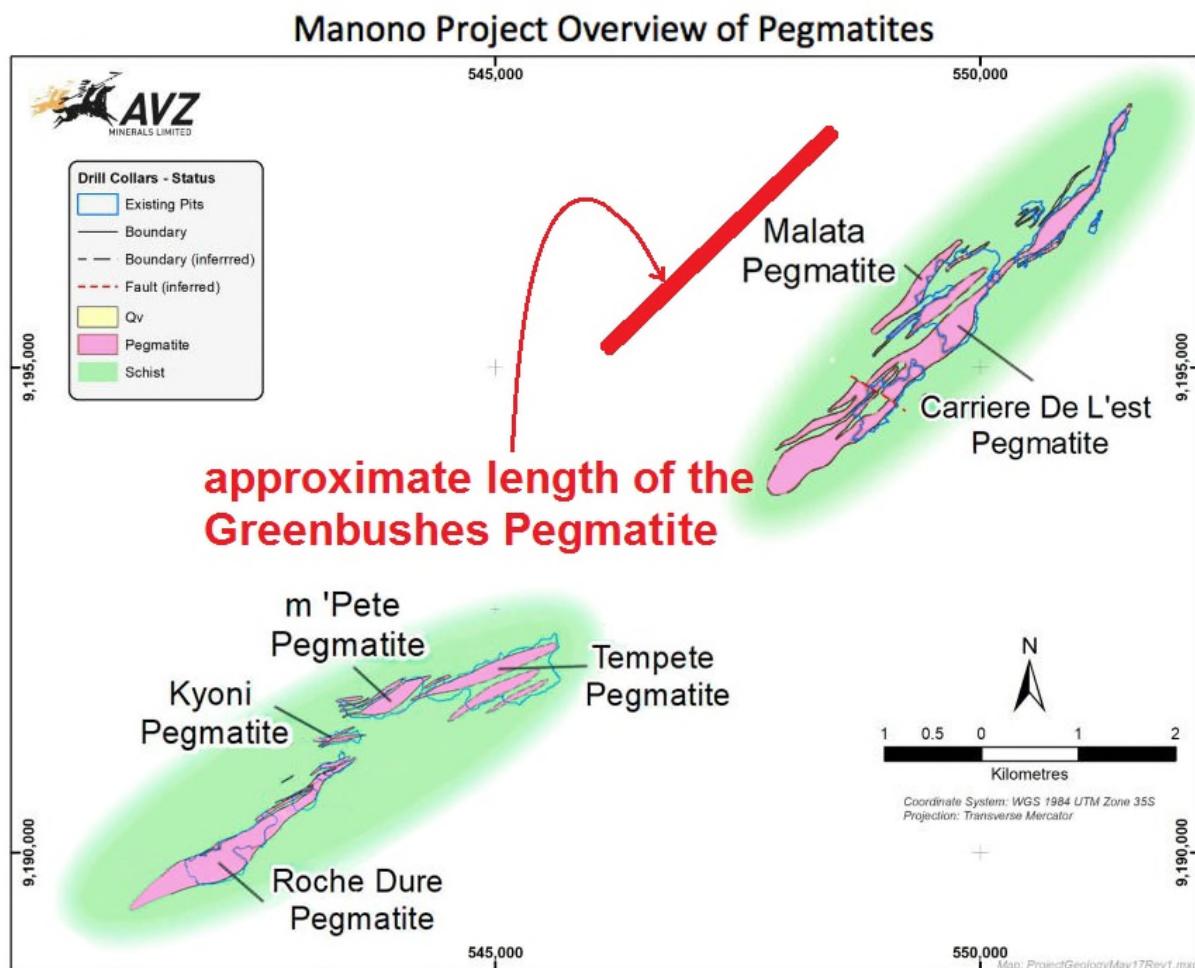

Figure 2: Comparison of the length of the Manono Project Pegmatites with the Greenbushes Pegmatite

Trenching

A total of 37 reconnaissance trenches have been excavated to date for a total length of 2,797m. From these trenches 1,205 composite rock-chip samples were collected, mostly from 2m intervals.

Assay results have been received for 511 samples (from 6 trenches) and demonstrate the widespread occurrence of distinct lithium (Li) anomalism (Table 1 and Figure 3). Refer to Appendix 1 for detailed trench results. Results for 694 samples are pending. Samples were assayed using a Peroxide Fusion digest with ICP-OES/MS finish and the concentrations of 54 elements were determined. Location data for trenches are presented in Appendix 2.

Table 1: Manono Project trench results

Trench ID (initial use)	Trench ID (current use)	Intervals greater than 0.5% Li ₂ O	Comment
Roche Dure TR001	T1	nil	extremely weathered pegmatite
Roche Dure TR002	T2	6m-14m; 8m @ 0.54% Li ₂ O	weathered pegmatite
		26m-48m; 22m @ 0.65% Li ₂ O	weathered pegmatite
		56m-60m; 4m @ 0.81% Li ₂ O	weathered pegmatite
Roche Dure TR003	T3	0m-30m; 30m @ 0.76% Li ₂ O	weathered pegmatite
		124m - 128m; 4m @ 1.01% Li ₂ O	relatively unweathered pegmatite
Roche Dure TR004	T4	136m - 140m; 4m @ 0.63% Li ₂ O	weathered pegmatite
Roche Dure TR005	T5	0m-197m; 197m @ 0.56% Li ₂ O	most of samples weathered pegmatite
		includes 12m-40m; 38m @ 1.29% Li ₂ O	relatively unweathered pegmatite
		and 60m-89m; 29m @ 1.54% Li ₂ O	relatively unweathered pegmatite
Malata TR001	T14	98m-124m; 26m @ 0.54% Li ₂ O	weathered pegmatite

Manono Site Trenches

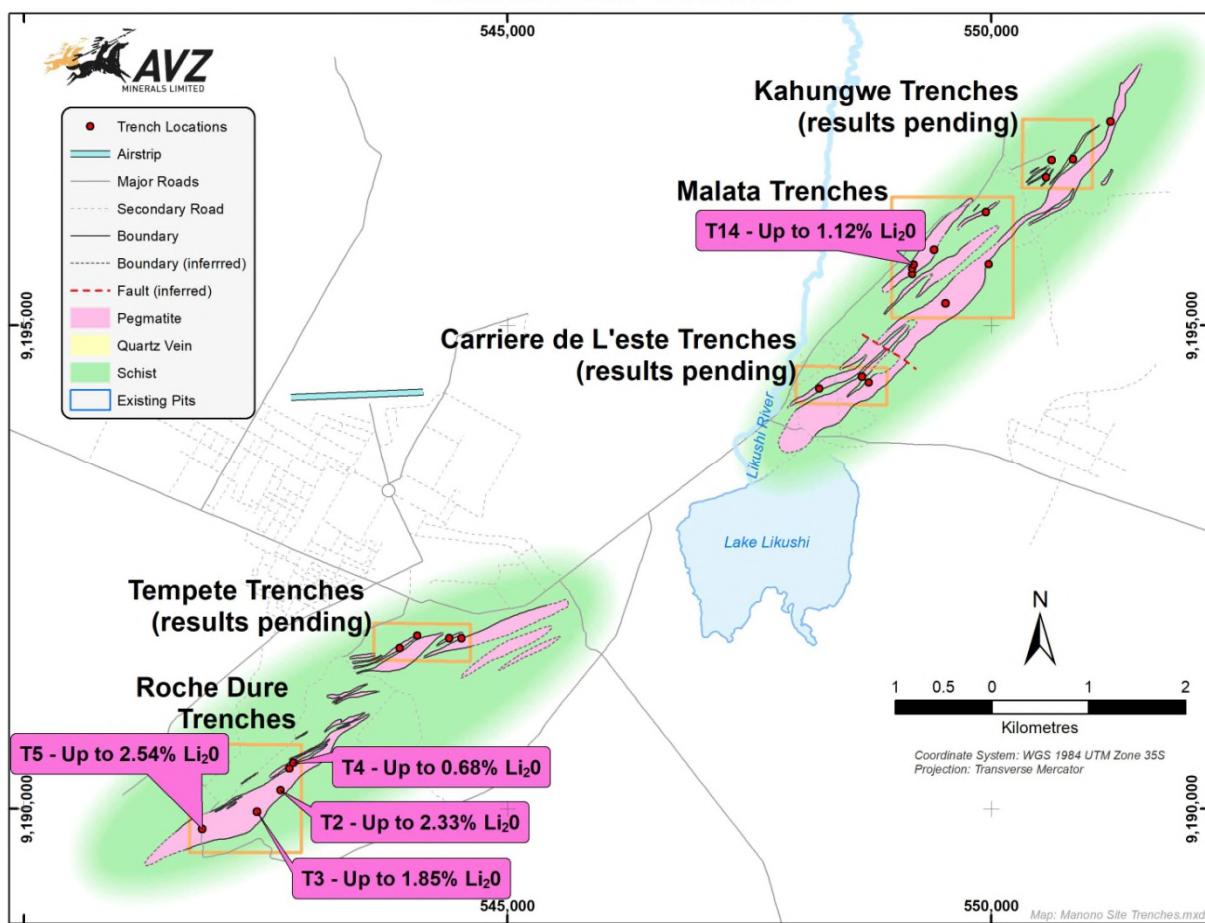

Figure 3: Location of trenches, with significant results shown

The high Li₂O concentrations reported correspond to samples collected from trench intervals cut into relatively fresh, less leached pegmatite and are indicative of what is expected in drill core assays. Conversely, the samples collected from outcrops of highly weathered pegmatite contain much lower concentrations of lithium but are still indicative of a well mineralised system.

This near-surface weathering-induced lithium depletion is typical of weathered pegmatites. The weathering profile at Manono indicates that the depth of weathering is between 30m and 60m below surface. The Roche Dure pegmatite has been intercepted in drilling to a vertical depth of 225m and remains open at depth down dip. Some very high tin concentrations were also recorded, as would be expected given the historical production of tin from the area.

Drilling Update

The Company would also like to provide an update on the initial drill program which was recently completed, for a total of 1,734 metres. Initial assay results are expected in early August. Delays have been due to the late delivery of spare parts for the core saw and third party delays in exporting of the samples. These issues have now been remedied.

The true thickness of the Roche Dure pegmatite currently being drill tested is estimated to be up to 220 metres. Spodumene ranging between 5% to 25% of whole rock volume and minor cassiterite/coltan is clearly visible in sections of the core.

Conceptual Exploration Target

Given the size and mineralised nature of the pegmatites at Manono, the Company has generated an exploration target tonnage of between 400 and 800Mt at grade between 1% to 1.5% Li₂O within pegmatite ore. The potential quantity and grade as stated, is conceptual in nature as there has been insufficient exploration to estimate a Mineral Resource and it is uncertain if further exploration will result in the estimation of a Mineral Resource.

This conceptual target is based on detailed prospect scale mapping, some 37 trenches totalling 2,800m producing 1,200 assay samples and approximately 1,750m of logs relating to diamond core drilling from 7 drill holes as completed to-date. The Company intends to embark on a significant drilling program to enable drill definition of Mineral Resources to JORC 2012 standard.

Strengthening of the Technical Team

Consultant lithium specialist Mr Peter Spitalny (MAusIMM) has recently completed a site visit to the Manono Project with the objective of assessing the Project's geological potential, reviewing AVZ's exploration standards and procedures and commenting on AVZ's planned exploration program. Peter will assist AVZ in an ongoing advisory role.

Peter has been involved in mineral exploration for over 25 years, primarily focussed on exploration for lithium, gold, nickel and base-metals. Peter has evaluated and been involved in exploration of more than 20 pegmatite fields in Western Australia, South America (Brazil) and Africa (Namibia and the Democratic Republic of the Congo) in which LCT (lithium) pegmatites are present. Peter has sufficient experience relating to pegmatite mineralisation to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'.

Competent Persons Statement

The information in this report that relates to Exploration Results and Exploration Targets is based on information compiled by Mr. Peter Spitalny, a Competent Person whom is a Member of the Australasian Institute of Mining and Metallurgy. Mr. Spitalny is a full-time employee of Hanree Holdings Pty Ltd. Mr Spitalny has sufficient experience that is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Spitalny consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

* - A 'Competent Person' as defined by the JORC 2012 code for reporting is a minerals industry professional who is a Member or Fellow of The Australasian Institute of Mining and Metallurgy, or of the Australian Institute of Geoscientists, or of a 'Recognised Professional Organisation' (RPO), as included in a list available on the JORC and ASX websites. These organisations have enforceable disciplinary processes including the powers to suspend or expel a member.

A Competent Person must have a minimum of five years relevant experience in the style of mineralisation or type of deposit under consideration and in the activity which that person is undertaking. If the Competent Person is preparing documentation on Exploration Results, the relevant experience must be in exploration. If the Competent Person is estimating, or supervising the estimation of Mineral Resources, the relevant experience must be in the estimation, assessment and evaluation of Mineral Resources. If the Competent Person is estimating, or supervising the estimation of Ore Reserves, the relevant experience must be in the estimation, assessment, evaluation and economic extraction of Ore Reserves.

JORC Code, 2012 Edition – Table 1

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code Explanation	Commentary
Sampling techniques	Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc.). These examples should not be taken as limiting the broad meaning of sampling.	The trenches were sampled through collection of rockchips chiselled or knapped from the floor of the trench as a continuous channel-sample over 2m intervals.
	Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.	The continuous channel sampling provides 2m composite samples that are representative of the sampled interval in the locality of sampling but cannot be considered representative of the entire pegmatite body.
	Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information.	The channel sampling of the trenches was completed according to industry standards; the 2m composite channel samples were comprised of rock chips, had a mass of 2kg-3kg and equal quantities of sample were collected from throughout the sample interval.
Drilling techniques	Drill type (e.g. core, reverse circulation, open hole hammer, rotary air blast, auger, Bangka, sonic, etc.) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face sampling bit or other type, whether core is oriented and if so, by what method, etc.).	This information release does not report dril sampling or results.
Drill sample recovery	Method of recording and assessing core and chip sample recoveries and results assessed.	This information release does not report dril sampling or results.
	Measures taken to maximise sample recovery and ensure representative nature of the samples.	This information release does not report dril sampling or results.
	Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.	This information release does not report dril sampling or results.
Logging	Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.	This information release does not report dril sampling or results.
	Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc.) photography	Logging of the trenches was both quantitative and qualitative. The Lithology excavated along the length was logged qualitatively, while the interval of the trench sampled was measured from a set end-point.
	The total length and percentage of the relevant intersections logged.	This information release does not report dril sampling or results.

Sub-sampling techniques and sample preparation	If core, whether cut or sawn and whether quarter, half or all core taken.	This information release does not report dril sampling or results.
	If non-core, whether rifled, tube sampled, rotary split, etc. and whether sampled wet or dry.	This information release does not report dril sampling or results.
	For all sample types, the nature, quality and appropriateness of the sample preparation technique.	The samples from the trench were collected as channel samples comprised of rock-chips. The bagged samples were sent to SGS Lubumbashi (DRC) where they were crushed and pulverized to a pulp. A 120g subset was split from the pulp and sent to SGS Randfontein (RSA) for analytical determination.
	Quality control procedures adopted for all subsampling stages to maximise representivity of samples.	Standard sub-sampling procedures are utilized by SGS Lubumbashi at all stages of sample preparation such that each sub-sample split is representative of the whole it was derived from.
	Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling	No duplicate sampling has been undertaken for the trenching program. In-house laboratory duplicates have been relied upon. For first-pass reconnaissance sampling this is adequate.
Quality of assay data and laboratory tests	Whether sample sizes are appropriate to the grain size of the material being sampled.	Sampling of pegmatites is problematic because of the varying, and frequently very coarse grain size. Of all the field surface sampling methods, channel sampling is considered to give the most reliable indication of the mineralization present as the resultant sample may incorporate a broader range of pegmatite material. The 2kg-3kg mass of the samples is appropriate to the sampling methodology and the material being sampled.
	The nature, quality and appropriateness of the Assaying and laboratory procedures used and whether the technique is considered partial or total.	The rock-chip channel samples from the trenches were submitted to SGS Randfontein (Johannesburg) and analysed using method ICP90A. This consists of a Sodium Peroxide Fusion followed by dissolution of the fused mass by dilute acid and finally determination of elemental concentrations using combined ICP-OES and ICP-MS methods. Sodium Peroxide Fusion is a total digest and considered the preferred method of assaying pegmatite samples.
	For geophysical tools, spectrometers, handheld XRF instruments, etc., the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.	There were no geophysical tools, spectrometers, handheld XRF instruments used.
Verification of sampling and assaying	Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.	As sampling undertaken was of a first pass nature, laboratory introduced standards, blanks and repeats were relied upon.
	The verification of significant intersections by either independent or alternative company personnel.	No verification exploration work has so far been undertaken.
	The use of twinned holes.	This information release does not report dril sampling or results.
	Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.	The data from previous exploration are currently stored in hardcopy and digital format on site. A hard drive copy of this is located at the administration office in country and all data is uploaded to the GIS consultants' database in Perth, WA.
	Discuss any adjustment to assay data.	Samples were assayed for a suite of 54 elements but the presented data has been reduced to include Li, Sn, Ta and Nb. In addition Li ₂ O has been included. It has been calculated from the reported assay result for Li in ppm.

		The calculation is %Li ₂ O = (ppmLi x 2.153)/10000 and the results have been rounded to the second decimal place.
Location of data points	Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.	The start-point, end-point and bends in the trenches have been surveyed using handheld GPS devices, giving an accuracy of +/- 3m in open-ground.
	Specification of the grid system used.	WGS_84 UTM Zone 35S
	Quality and adequacy of topographic control.	No survey has been undertaken. Hand held GPS coordinates have been utilized to locate sampling to date
Data spacing and distribution	Data spacing for reporting of Exploration Results.	Sampling undertaken to date was of a reconnaissance nature and wide spread along specific structures.
	Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.	Not applicable as no resource estimation. Sampling undertaken to date was of a reconnaissance nature and wide spread along geologic bodies.
	Whether sample compositing has been applied.	By their nature, channel samples are composite samples
Orientation of data in relation to geological structure	Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.	Not applicable to the current sampling.
	If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.	This information release does not report dril sampling or results.
Sample security	The measures taken to ensure sample security.	Chain of custody is maintained by AVZ personnel on-site to Lubumbashi. At Lubumbashi, the prepped samples (pulps) are sealed into a box and delivered by DHL to SGS Randfontein.
Audits or reviews	The results of any audits or reviews of sampling techniques and data.	The sampling techniques and data have been reviewed and the assay results are believed to give a reliable indication of the lithium mineralisation within the samples.

Section 2 Reporting of Exploration Results

(Criteria listed in the preceding section also apply to this section.)

Criteria	JORC Code Explanation	Commentary
Mineral tenement and land tenure status	Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.	The Manono licence has been recently awarded as a Research Permit PR 13359 issued on the 28th December 2016 and valid for 5 years. All indigenous title is cleared and there are no other known historical or environmentally sensitive areas. A PAR environmental report has been lodged and is awaiting clearance from the Government department responsible for this, CAMI
	The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.	See above, no other known impediments.
Exploration done by other parties	Acknowledgment and appraisal of exploration by other parties.	<p>Within PR13359 exploration of relevance was undertaken by Geomines whom completed a program of drilling between 1949 and 1951. The drilling consisted of 42 vertical holes drilled to a general depth of around 50 to 60m and reaching the -80m level. Drilling was carried out on 12 sections at irregular intervals ranging from 50m to 300m, and over a strike length of some 1,100m. Drill spacing on the sections varied from 50 to 100m. The drilling occurred in the RD Pit only, targeting the fresh pegmatite in the Kitotolo sector of the project area.</p> <p>The licence area has been previously mined for tin and tantalum including "coltan" through a series of open pits over a total length of approximately 10km excavated by Zairetain sprl. More than 60Mt of material was mined from three major pits and several subsidiary pits. Ore was crushed and then upgraded through gravity separation to produce a concentrate of a reported 72%Sn. There are no reliable records available of tantalum or lithium recovery as tin was the primary mineral being recovered.</p> <p>Apart from the mining excavations and the drilling program, there has been very limited exploration work within the Manono extension licences.</p>

Geology	<p>Deposit type, geological setting and style of mineralisation.</p>	<p>The Project lies within the mid-Proterozoic Kibaran Belt - an intracratonic domain, stretching for over 1,000 km through Katanga and into southwest Uganda. The belt strikes predominantly SW-NE and is truncated by the N-S to NNW-SSE trending Western Rift system.</p> <p>The Kibaran comprises a sedimentary and volcanic sequence that has been folded, metamorphosed and intruded by at least three separate phases of granite. The latest granite phase (900 to 950 My ago) is assigned to the Katangan cycle and is associated with widespread vein and pegmatite mineralization containing tin, tungsten, tantalum, niobium, lithium and beryllium. Deposits of this type occur as clusters and are widespread throughout the Kibaran terrain. In the DRC, the Katanga Tin Belt stretches over 500 km from near Kolwezi in the southwest to Kalemie in the northeast comprising numerous occurrences and deposits of which the Manono deposit is the largest.</p> <p>The geology of the Manono area is poorly documented and no reliable maps of local geology were observed. Recent mapping by AVZ has augmented the overview provided by Bassot and Morio (1989) and has led to the following description.</p> <p>The Manono Project pegmatites are hosted by a series of mica schists and by amphibolite in some locations. These host rocks have a steeply dipping penetrative foliation that appears to be parallel to bedding. There are numerous bodies of pegmatite, the largest of which have sub-horizontal to moderate dips, with dip direction being towards the southeast. The pegmatites post-date metamorphism, with all primary igneous textures intact. They cross-cut the host-rocks but despite their large size, the contact deformation and metasomatism of the host rocks by the intrusion of the pegmatites seems minor. The absence of significant deformation of the schistosity of the host rocks implies that the pegmatites intruded brittle rocks.</p> <p>The pegmatites constitute a pegmatite swarm in which the largest pegmatites have an apparent en-echelon arrangement in a linear zone more than 12km long. The pegmatites are exposed in two areas; Manono in the northeast, and Kitotolo in the southwest. These areas are separated by a 2.5 km section of alluvium-filled floodplain which contains Lake Lukushi. At least one large pegmatite extends beneath the floodplain.</p> <p>The pegmatites are members of the LCT-Rare Element group of pegmatites and within the pegmatite swarm there are LCT Albite-spodumene pegmatites and LCT Complex (spodumene sub-type) pegmatites.</p>
Drill hole Information	<p>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:</p> <ul style="list-style-type: none"> • easting and northing of the drill hole collar • elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar • dip and azimuth of the hole • down hole length and interception depth • hole length. 	<p>This information release does not report dril sampling or results.</p>
	If the exclusion of this information is	This information release does not report dril sampling or

	justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.	results.
Data aggregation methods	In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades are usually Material and should be stated.	All results being reported for trenches are based on 2 metre interval lengths and have had sample intervals selected by AVZ personnel based on geological intervals and boundaries. No top cut has been applied. A general bottom cut of 0.25% Li2O has been imposed for any aggregated assay interval reported where that aggregated assay interval is less than 10m in length and less than 0.25% Li2O. No geostatistical methods were employed in applying the bottom cut. At this stage it is considered that an insufficient data set has been collected to allow geostatistical methods of any relevance. Methodology will change as the collected dataset increases
	Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.	All assays reported are weighted averaged to the individual sample lengths combined over the interval.
	The assumptions used for any reporting of metal equivalent values should be clearly stated.	No metal equivalent values reported. No topcut has been applied .
Relationship between mineralisation widths and intercept lengths	These relationships are particularly important in the reporting of Exploration Results. If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported	The historic core holes were drilled at -90 dip to intercept mineralisation generally dipping -30 to sub-horizontal. Recorded intercept lengths will therefore be greater than true width of mineralisation. Given the widely spaced reconnaissance nature of the current drilling the geometry of the mineralisation reported is not known and true width is not known. Current surface sampling results within trenches were generally oriented perpendicular to the pegmatite strike and as such are generally collected at 2 metres across strike width.
	If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g. 'down hole length, true width not known').	As above.
Diagrams	Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.	Refer to this press release body of text
Balanced reporting	Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.	Due to the nature of the historical drilling and lack of adequate records and survey control data available, they are to be considered indicative only and not material.

Other substantive exploration data	Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.	No further data available.
Further work	The nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large-scale step-out drilling).	Further work will include mapping, soil sampling and bed rock sampling for geochemical anomalies to identify prospective target zones and then RC and Diamond drill testing of the higher priority targets. Diamond drilling will be included in subsequent phases of drilling,
	Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.	These will be provided when drilling is reported.
