“The presence of mechanoreceptive and nociceptive nerve endings in cervical facet capsules proves that these tissues are monitored by the CNS and implies that neural input from the facets is important to proprioception and pain sensation in the cervical spine.”
Immunohistochemical demonstration of nerve fibers in the synovial fold of the human cervical facet joint

Satoshi Inami a,*, Takashi Shiga b, Akihito Tsujino a, Takeshi Yabuki c, Nobuo Okado b, Naoyuki Ochiai a

Abstract

The role of the intra-articular synovial fold as a source of facet joint pain is unclear, because the nature of nociceptive innervation in lumbar synovial folds is controversial, and there have been no such studies in cervical synovial folds. The present study aimed to demonstrate the presence of nerve fibers including nociceptive fibers in synovial folds of human cervical facet joints using immunohistochemistry. Synovial folds of cervical facet joints removed from patients undergoing cervical spine laminoplasty were analyzed immunohistochemically using antibodies to protein gene product 9.5, β III-tubulin, substance P and calcitonin gene-related peptide. Many nerve fibers immunoreactive for protein gene product 9.5 and β III-tubulin were demonstrated both around blood vessels and as free fibers in the stroma of the synovial fold. Also, immunostaining showed the presence of free nerve fibers immunoreactive for substance P and calcitonin gene-related peptide in the stroma. The presence of putative nociceptive fibers in cervical synovial folds supports a possible role for these structures as a source of cervical facet joint pain. © 2001 Orthopaedic Research Society. Abstract

The ligaments were considered, over several centuries, as the major restraints of the joints, keeping the associated bones in position and preventing instability, e.g. their separation from each other and/or mal-alignment. This project, conducted over 25 years, presents the following hypothesis:
The hypothesis

The hypothesis consists of the following sequential steps:

1. Single trauma or cumulative microtrauma causes subfailure injury of the spinal ligaments and injury to the mechanoreceptors embedded in the ligaments.
2. When the injured spine performs a task or it is challenged by an external load, the transducer signals generated by the mechanoreceptors are corrupted.
3. Neuromuscular control unit has difficulty in interpreting the corrupted transducer signals because there is spatial and temporal mismatch between the normally expected and the corrupted signals received.
4. The muscle response pattern generated by the neuromuscular control unit is corrupted, affecting the spatial and temporal coordination and activation of each spinal muscle.
5. The corrupted muscle response pattern leads to corrupted feedback to the control unit via tendon organs of muscles and injured mechanoreceptors, further corrupting the muscle response pattern.

6. The corrupted muscle response pattern produces high stresses and strains in spinal components leading to further subfailure injury of the spinal ligaments, mechanoreceptors and muscles, and overload of facet joints.
7. The abnormal stresses and strains produce inflammation of spinal tissues, which have abundant supply of nociceptive sensors and neural structures.
8. Consequently, over time, chronic back pain may develop. The subfailure injury of the spinal ligament is defined as an injury caused by stretching of the tissue beyond its physiological limit, but less than its failure point [48].
Fig. 1 Spinal stabilizing system. It consists of three subsystems: spinal column, spinal muscles, and neuromuscular control unit. The spinal column has two functions: structural—to provide intrinsic mechanical stability, and transducer—to generate signals describing spinal posture, motions, loads etc. via the mechanoreceptors. The neuromuscular control unit generates muscle response pattern to activate and coordinate the spinal muscles to provide muscle mechanical stability. There is feedback from the spinal muscles and mechanoreceptors to the control unit. (Adapted from Panjabi 1992)
Fig. 2 Normal circumstances. The intact mechanoreceptors send transducer signals to the neuromuscular control unit, which evaluates the transducer signals and sends out muscle response pattern to coordinate the activation of individual spinal muscles. There is feedback from the muscle spindles and golgi tendon organs of the muscles and mechanoreceptors of the ligaments to the neuromuscular control unit. Under normal circumstances, there are no adverse consequences.
Fig. 3: Subfailure injuries of the ligaments. The injured mechanoreceptors send out corrupted transducer signals to the neuromuscular control unit, which finds spatial and temporal mismatch between the expected and received transducer signals, and, as a result, there is muscle system dysfunction and corrupted muscle response pattern is generated. Consequently, there are adverse consequences: higher stresses, strains, and even injuries in the ligaments, mechanoreceptors, and muscles. There may also be muscle fatigue and excessive facet loads. These abnormal conditions produce neural and ligament inflammation, and over time, chronic back pain.

- **Injured Mechanoreceptors**
  - Corrupted Transducer signals

- **Neuromuscular Control Unit**
  - Corrupted Response
  - Feedback

- **Corrupted Muscle Response Pattern**
  - Coordination of individual muscle activation

- **Chronic Back Pain**

- **Tissue Inflammation**

- **Adverse Consequences**
  - Higher stresses/strains and injuries in ligaments, mechanoreceptors, and muscles
  - Muscle fatigue
  - Higher facet loads
Facet joints are implicated as a major source of neck and low-back pain. Both cervical and lumbar facet syndromes have been described in the medical literature. Biomechanical studies have shown that lumbar and cervical facet-joint capsules can undergo high strains during spine-loading. Neuroanatomic studies have demonstrated free and encapsulated nerve endings in facet joints as well as nerves containing substance P and calcitonin gene-related peptide. Neurophysiologic studies have shown that facet-joint capsules contain low-threshold mechanoreceptors, mechanically sensitive nociceptors, and silent nociceptors. Inflammation leads to decreased thresholds of nerve endings in facet capsules as well as elevated baseline discharge rates. Recent biomechanical studies suggest that rear-end motor-vehicle impacts give rise to excessive deformation of the capsules of lower cervical facet joints. Still unresolved is whether this stretch is sufficient to activate nociceptors in the joint capsule.

To answer this question, recent studies indicate that low stretch levels activate proprioceptors in the facet-joint capsule. Excessive capsule stretch activates nociceptors, leads to prolonged neural afterdischarges, and can cause damage to the capsule and to axons in the capsule. In instances in which a whiplash event is severe enough to injure the joint capsule, facet capsule overstretch is a possible cause of persistent neck pain.
Teased nerve roots were monitored as the facet capsule was stretched & electrically stimulated in rats.

Neuromechanical Characterization of In Vivo Lumbar Spinal Manipulation. Part II. Neurophysiological Response

Christopher J. Colloca, DC, Tony S. Keller, PhD, and Robert Gunzburg, MD, PhD

Abstract

Objective: To simultaneously quantify vertebral motions and neuromuscular and spinal nerve root responses to mechanical force, manually assisted, short-lever spinal manipulative thrusts.

Methods: Four patients underwent lumbar laminarhectomy to decompress the central spinal canal and neuroforamina, as clinically indicated. Prior to decompression, finely threaded, 1.8-mm diameter intraosseous pins were rigidly fixed to the lumbar spinous process (L1 or L3) using fluoroscopic guidance, and a high-frequency, low-noise, 10-g, triaxial accelerometer was mounted to the pin. Following decompression, 4 needle electromyographic (nEMG) electrodes were inserted into the multifidus musculature adjacent to the pin mount bilaterally, and 2 bipolar platinum electrodes were cradled around the left and right S1 spinal nerve roots. With the spine exposed, spinal manipulative thrusts were delivered internally to the lumbosacral spinous processes and facet joints and externally by contacting the skin overlying the respective spinal landmarks using 2 force settings (~30 N, <5 milliseconds (ms); ~150 N, <5 ms) and 2 force vectors (posteroanterior and superior; posteroanterior and inferior).

Results: Spinal manipulative thrusts resulted in positive electromyographic (EMG) and compound action potential (CAP) responses that were typically characterized by a single voltage potential change lasting several milliseconds in duration. However, multiple EMG and CAP discharges were observed in numerous cases. The temporal relationship between the initiation of the mechanical thrust and the neurophysiologic response to internal and external spinal manipulative therapy (SMT) thrusts ranged from 2.4 to 18.1 ms and 2.4 to 28.6 ms for EMG and CAP responses, respectively. Neurophysiologic responses varied substantially between patients.

Conclusions: Vertebral motions and resulting spinal nerve root and neuromuscular reflex responses appear to be temporally related to the applied force during SMT. These findings suggest that intersegmental motions produced by spinal manipulation may play a prominent role in eliciting physiologic responses. (J Manipulative Physiol Ther 2003; 26:579-91)

Biomechanical and Neurophysiological Responses to Spinal Manipulation in Patients With Lumbar Radiculopathy

Christopher J. Colloca, DC, Tony S. Keller, PhD, and Robert Gunzburg, MD, PhD

Abstract

**Objective:** The purpose of this study was to quantify in vivo vertebral motions and neurophysiological responses during spinal manipulation.

**Methods:** Nine patients undergoing lumbar decompression surgery participated in this study. Spinal manipulative thrusts (SMTs) (~5 ms: 30 N [Sham], 88 N, 117 N, and 150 N [max]) were administered to lumbar spine facet joints (FJs) and spinous processes (SPs) adjacent to an intramuscular nerve root with an attached triaxial accelerometer and bipolar electrodes cradled around the S1 spinal nerve roots. Peak baseline amplitude compound action potential (CAP) response and peak-peak amplitude axial (AX), anterior-posterior (PA), and medial-lateral (ML) acceleration time and displacement time responses were computed for each SMT. Within-subject statistical analyses of the effects of contact point and force magnitude on vertebral displacements and CAP responses were performed.

**Results:** SMTs (≥ 88 N) resulted in significantly greater peak-to-peak ML, PA, and AX vertebral displacements compared with sham thrusts (P < .002). SMTs delivered to the FJs resulted in approximately 3-fold greater ML motions compared with SPs (P < .001). SMTs over the SPs resulted in significantly greater AX displacements compared with SMTs applied to the FJs (P < .05). Seventy-five percent of SMTs resulted in positive CAP responses with a mean latency of 12.0 ms. Collectively, the magnitude of the CAP responses was significantly greater for max setting SMTs compared with sham (P < .01).

**Conclusions:** Impulse SMTs in human subjects were found to stimulate spinal nerve root responses that were temporally related to the onset of vertebral motion. Further work, including examination of the frequency and force duration dependency of SMT, is necessary to elucidate the clinical relevance of enhanced or absent CAP responses in patients. (J Manipulative Physiol Ther 2004;27:1-15)

**Key Indexing Terms:** Chiropractic Manipulation; Vertebral Motion; Neurophysiology
Objective: To quantify in vivo spinal motions and coupling patterns occurring in human subjects in response to mechanical force, manually assisted, short-lever spinal manipulative thrusts (SMTs) applied to varying vertebral contact points and utilizing various excursion (force) settings.

Methods: Triaxial accelerometers were attached to intrasosseous pins rigidly fixed to the L1, L3, or L4 lumbar spinous process of 4 patients (2 male, 2 female) undergoing lumbar decompressive surgery. Lumbar spine acceleration responses were recorded during the application of 14 externally applied posteroanterior (PA) impulsive SMTs (4 force settings and 3 contact points) in each of the 4 subjects. Displacement time responses in the PA, axial (AX), and medial-lateral (ML) axes were obtained, as were intervertebral (L3-4) motion responses in 1 subject. Statistical analysis of the effects of facet joint (FJ) contact point and force magnitude on peak-to-peak displacements was performed. Motion coupling between the 3 coordinate axes of the vertebrae was examined using a least squares linear regression.

Results: SMT forces ranged from 30 N (lowest setting) to 150 N (maximum setting). Peak-to-peak ML, PA, and AX vertebral displacements increased significantly with increasing applied force. For thrusts delivered over the FJs, pronounced coupling was observed between all axes (AX-ML, AX-PA, PA-ML) (linear regression, $R^2 = 0.35-0.52$, $P < .001$), whereas only the AX and PA axes showed a significant degree of coupling for thrusts delivered to the spinous processes (SPs) (linear regression, $R^2 = 0.82$, $P < .001$). The ML and PA motion responses were significantly ($P < .05$) greater than the AX response for all SMT force settings. PA vertebral displacements decreased significantly ($P < .05$) when the FJ contact point was caudal to the pin compared with FJ contact cranial to the pin. FJ contact at the level of the pin produced significantly greater ML vertebral displacements in comparison with contact above and below the pin. SMTs over the spinous processes produced significantly ($P < .05$) greater PA and AX displacements in comparison with ML displacements. The combined ML, PA, and AX peak-to-peak displacements for the 4 force settings and 2 contact points ranged from 0.15 to 0.66 mm, 0.15 to 0.81 mm, and 0.07 to 0.45 mm, respectively. Intervertebral motions were of similar amplitude as the vertebral motions.

Conclusions: In vivo kinematic measurements of the lumbar spine during the application of SMTs over the FJs and SPs corroborate previous spinous process measurements in human subjects. Our findings demonstrate that PA, ML, and AX spinal motions are coupled and dependent on applied force and contact point. (J Manipulative Physiol Ther 2003;26:567-78)

BIOMECHANICAL QUANTIFICATION OF PATHOLOGIC MANIPULABLE SPINAL LESIONS: AN IN VIVO OVINE MODEL OF SPONDYLOLYSIS AND INTERVERTEBRAL DISC DEGENERATION

Christopher J. Colloca, DC, a Robert Gunzburg, MD, PhD, b Brian J. Freeman, MD, c Marek Szpalski, MD, d Mostafa Affi, PhD, e and Robert J. Moore, PhD f

ABSTRACT

Objective: The purposes of this study were to quantify the biomechanical and pathologic consequences of surgically induced spinal lesions and to determine their response to spinal manipulation (SMT) in an in vivo ovine model.

Methods: Of 24 Merino sheep, 6 received L5 spondyloytic defects, 6 received L1 annular lesions, and 12 served as respective controls. Dorsoventral (DV) stiffness was assessed using oscillatory loads (2-12 Hz). Two SMT force-time profiles were administered in each of the groups using a randomized and repeated-measures design. Stiffness and the effect of SMT on the DV motions and multifidus needle electromyographic responses were assessed using a repeated-measures analysis of variance (α = .05). Postmortem histologic analysis and computed tomography validated the presence of lesions.

Results: L5 DV stiffness was significantly increased (40.2%) in the spondyloysis (6.28 N/mm) compared with the L5 control group (4.48 N/mm) (P < .03). Spinal manipulations delivered to the spondyloysis group resulted in less DV vertebral displacement (P < .01) compared with controls. Dorsoventral stiffness of the disc degeneration group was 5.66 N/mm, 94.5% greater than in the L1 control group (2.91 N/mm) (P < .01). One hundred-millisecond SMTs resulted in significantly reduced DV displacements in the disc degeneration group compared with the L1 control group (P < .01). Animals in the disc degeneration group showed a consistent 25% to 30% reduction in needle electromyographic responses to all SMTs.

Conclusions: Quantifiable objective evidence of spinal lesions and their response to SMT were confirmed in this study. Neuromechanical alterations provide novel insights into quantifying manipulable spinal lesions and a means to biomechanically assess SMT outcomes. (J Manipulative Physiol Ther 2012:35:354-366)

THREE-DIMENSIONAL VERTEBRAL MOTIONS PRODUCED BY MECHANICAL FORCE SPINAL MANIPULATION

Tony S. Keller, PhD, a Christopher J. Colloca, DC, b Robert J. Moore, PhD, c Robert Gunzburg, MD, PhD, d Deed E. Harrison, DC, e and Donald D. Harrison, DC f

ABSTRACT

Objective: The aim of this study was to quantify and compare the 3-dimensional intersegmental motion responses produced by 3 commonly used chiropractic adjusting instruments.

Methods: Six adolescent Merino sheep were examined at the Institute for Medical and Veterinary Science, Adelaide, Australia. In all animals, triaxial accelerometers were attached to intravenous pins rigidly fixed to the L1 and L2 spinous processes under fluoroscopic guidance. Three handheld mechanical force chiropractic adjusting instruments (Chiropractic Adjusting Tool [CAT], Activator Adjusting Instrument IV [Activator IV], and the Impulse Adjusting Instrument [Impulse]) were used to randomly apply posteroanterior (PA) spinal manipulative thrusts to the spinous process of T12. Three force settings (low, medium, and high) and a fourth setting (Activator IV only) were applied in a randomized repeated measures design. Acceleration responses in adjacent segments (L1 and L2) were recorded at 5 kHz. The multiaxial intersegmental (L1-L2) acceleration and displacement response at each force setting was computed and compared among the 3 devices using a repeated measures analysis of variance (α = .05).

Results: For all devices, intersegmental motion responses were greatest for axial, followed by PA and medial-lateral (ML) measurement axes for the data examined. Displacements ranged from 0.11 mm (ML axis, Activator IV low setting) to 1.76 mm (PA axis, Impulse high setting). Compared with the mechanical (spring) adjusting instruments (CAT, Activator IV), the electromechanical Impulse produced the most linear increase in both force and intersegmental motion response and resulted in the greatest acceleration and displacement responses (high setting). Significantly larger magnitude intersegmental motion responses were observed for Activator IV vs CAT at the medium and high settings (P < .05). Significantly larger-magnitude PA intersegmental acceleration and displacement responses were consistently observed for Impulse compared with Activator IV and CAT for the high force setting (P < .05).

Conclusions: Larger-magnitude, 3D intersegmental displacement and acceleration responses were observed for spinal manipulative thrusts delivered with Impulse at most force settings and always at the high force setting. Our results indicate that the force-time characteristics of impulsive-type adjusting instruments significantly affect spinal motion and suggests that instruments can and should be tuned to provide optimal force delivery. Methods: Fifteen adolescent Merino sheep were examined. Tri-axial accelerometers were attached to intraosseous pins rigidly fixed to the L1 and L2 lumbar spinous processes under fluoroscopic guidance while the animals were anesthetized. A hand-held electromechanical chiropractic adjusting instrument (Impulse) was used to apply single and repeated force impulses (13 total over a 2.5 second time interval) at three different force settings (low, medium, and high) along the posteroanterior axis of the T12 spinous process. Axial (AX), posteroanterior (PA), and medial-lateral (ML) acceleration responses in adjacent segments (L1, L2) were recorded at a rate of 5000 samples per second. Peak-peak segmental accelerations (L1, L2) and intersegmental acceleration transfer (L1–L2) for each axis and each force setting were computed from the acceleration-time recordings. The initial acceleration response for a single thrust and the maximum acceleration response observed during the L2 multiple impulse trains were compared using a paired observations t-test (POTT, alpha = .05).

Intervertebral Disc Degeneration Reduces Vertebral Motion Responses

Christopher J. Colloca, DC,* Tony S. Kellier, PhD,† Robert J. Moore, PhD,‡ Robert Gunzburg, MD, PhD,§ and Deed E. Harrison, DC||

Study Design. A prospective in vivo experimental animal study.

Objective. To determine the effects of disc degeneration and variable pulse duration mechanical excitation on dorsoventral lumbar kinematic responses.

Summary of Background Data. In vitro and in vivo biomechanical studies have examined spine kinematics during posterioranterior loading mimicking spinal manipulation therapy (SMT), but few (if any) studies have quantified SMT loading-induced spinal motion responses in the degenerated intervertebral disc.

Methods. Fifteen sheep underwent a survival surgical procedure resulting in chronic disc degeneration of the L1-L2 disc. Ten age- and weight-matched animals served as controls. Uniform pulse dorsoventral mechanical forces (60 N) were applied to the L3 spinous processes using 10-, 100-, and 200-ms duration pulses mimicking SMT. L3 displacement and L2-L1 acceleration in the control group were compared with the degenerated disc group.

Results. Dorsoventral displacements increased significantly (p-value < 0.001) with increasing mechanical excitation pulse duration (control and degenerated disc groups). Displacements and L2-L1 acceleration transfer were significantly reduced (∼15% and ∼60%, respectively) in the degenerated disc group compared with control (100- and 200-ms pulse duration protocols, p < 0.01).

Conclusion. Dorsoventral vertebral motions are dependent on mechanical excitation pulse duration and are significantly reduced in animals with degenerated discs.

Key words: biomechanics, degeneration, intervertebral disc, manipulation, mobilization. Spine 2007;32: E544–E550

ing manual therapies. Progressive degenerative changes of the IVD are associated with increased age, trauma, and abnormal postural loading. Indeed, a large proportion of the population who receive manual therapies have some degree of disc disease. To influence the peripheral pain generator, patients with discogenic disease commonly undergo spinal manipulative therapy (SMT) with the primary goal of normalizing loads and improving spinal mobility.

A wide range of manual techniques have been developed providing clinicians with choices of force amplitude, speed, and vector among other variables of SMT delivery in patient care. Force-time characteristics, including the applied force magnitude, speed, and/or frequency, have therefore been attributed to the underlying mechanisms of SMT. Both in vitro and in vivo biomechanical studies have examined segmental and intersegmental displacements and vibration responses during SMT, but few (if any) studies have quantified SMT-induced spinal kinematics in the degenerated IVD.

The purpose of this experimental study was to examine the in vivo motion behavior of the normal disc and degenerated disc ovine lumbar spine subjected to varying mechanical excitation force-time profiles. Disc degeneration was established using a validated animal model. We hypothesized that vertebral kinematics would be reduced in animals with disc degeneration.

QUANTIFYING IN VIVO VERTEBRAL MOTIONS DURING IMPULSIVE SPINAL MANIPULATION

Christopher J. Colloca, DC1  ▶ Robert Gunzburg, MD, PhD2  ▶ Marek Szpalski, MD3  ▶ Mostafa Afifi, PhD4

1 Graduate Student, Biomechanics Laboratory, PhD Kinesiology Program, School of Nutrition and Health Promotion, Arizona State University, Tempe, Arizona, U.S.A.; 2Department of Orthopaedic Surgery, Edith Cavell (CAV), Brussels, Belgium; 3Department of Orthopaedic Surgery, Centre Hospital Moliere Longchamp, Brussels, Belgium; 4Faculty of Kinesiology, University of Calgary, Calgary, Alberta, Canada

Purpose
The purpose of this study is to quantify in vivo human lumbar spine motions during impulsive spinal manipulative therapy (SMT) delivery.

Methods
Tri-axial accelerometers were attached to intraosseous pins rigidly fixed to adjacent vertebrae at L4 and L5 spinous process of three patients undergoing lumbar decompressive surgery.

Lumbar spine acceleration responses were recorded during the application of 12 externally applied posteroanterior (PA) impulsive SMTs delivered by an Impulse iQ®.

Three force settings were delivered to two contact points (facet joint and spinous process) at two vectors (cranial and caudal) in a repeated measures design (n=144) in each subject.

Displacement-time responses in the PA, axial (AX) and medial-lateral (ML) axes were obtained from the acceleration-time histories using trapezoidal numerical integration.

Statistical analysis of the effects of contact point, force magnitude, and vector on peak-to-peak displacements was performed. Correlation of non-invasive stylus accelerations was compared to interosseous pin accelerations using least-squares linear regressions.
Results

Peak-to-peak ML, PA, AX vertebral motions increased significantly (p<.05) with increasing applied force.

Cranially directed SMTs created significantly greater L4-L5 motions compared to caudally directed thrusts (p<.01).

Contacts to the facet joints induced greater ML motions than those applied to the spinous processes (p<.01).
