Executive Summary

This report considers the objectives of the Maine Department of Health and Human Services (DHHS), Maine Center of Disease Control and Prevention (CDC): to identify substance use patterns in defined geographical areas, establish substance use trends, detect emerging substances, and provide information for policy development and program planning. It also highlights all the prevention priorities identified in the Maine CDC strategic prevention plan: underage drinking, high-risk drinking among 18- to 25-year-olds, misuse of prescription drugs among 18- to 25-year-olds, and marijuana use in 12- to 25-year-olds; it also monitors the progress being made to address these priorities. This report includes data available through the 2019 calendar year. Key findings of this report are highlighted below. All indicators and data source information are provided in the full report.

Consumption of Substances

Alcohol

- In 2019, among high school students who reported drinking in the past month (one in four), approximately one-third reported they had five or more drinks in a row at least once. Males appear more likely than females to participate in this behavior, as are older students relative to younger students. Results were the same in 2017.
- The highest binge drinking rates continue to be observed among the 18 to 24-year-olds, with about one in three reporting binge drinking within the past month.
- In 2018, just less than one in 10 pregnant women reported consuming any alcohol in their last trimester. Alcohol use rates observed a slight decrease from 2018.

Tobacco and Vaping Product Use

- Rates of tobacco use have progressively declined among youth and young adults in Maine but remain somewhat consistent among older age groups.
- In 2018, nearly 12 percent of pregnant women reported smoking cigarettes in their last trimester. Cigarette use rates observed a slight decrease from 2017 and were highest among younger women, as well as among those with lower levels of education.
- Nearly half of all high school students reported having ever used a vaping product and almost one third reported using in the past month. Among students who had ever used a vaping product, more than half reported that the last time they vaped it had nicotine, one quarter reported it was flavored, one in eight reported it was marijuana-based oil, and seven percent were unsure what was in the vapor. Past-month use of vapor products increased, nearly doubling from 2017 to 2019.
- E-cigarette use increased among adults 18 and over from 2016 (18%) to 2017 (21%). E-cigarette use has surpassed cigarette use in adult Mainers.
Marijuana

- In 2019, about one in five high school students reported using marijuana within the past month; rates have remained relatively steady in recent years.
- The highest rate of marijuana use among adults continues to be observed among 18 to 25-year-olds (35%). Marijuana use rates among adult Mainers have been steadily increasing over the past several years.

Prescription Drugs

- The percentage of high school students reporting they have misused a prescription medication in the past month decreased from 2017 (6%) to 2019 (5%). In 2019, about one in 10 high school students reported to have misused a prescription pain medication during their lifetime.
- Non-medical use of prescription pain relievers is more likely among young adults between the ages of 18 and 25 compared to adults age 26 and older. Seven percent of 18 to 25-year-olds reported having misused pain relievers in the past year.

Other Illegal Drugs

- In 2019, seven percent of high school students reported ever using inhalants, four percent reported ever using cocaine, and three percent reported ever using heroin. Lifetime rates for cocaine use decreased by one percentage point, but the lifetime use rates of inhalant, heroin and methamphetamine have remained unchanged since 2017.
- In 2017–18, seven percent of 18 to 25-year-olds, two percent of youth aged 12 to 17, and three percent of those 26 and older reported having used illicit drugs other than marijuana in the past year.
- In 2017–18, almost 7.5 percent of 18 to 25-year-olds and 1.5 percent of Mainers 26 and older reported they had used cocaine at least once in the past year, and 0.65 percent of Mainers 12 and older (approximately 8,737 residents) self-reported that they had used heroin within the past year; a slight increase from the previous year.

Consequences Resulting from Substance Use and Misuse

Criminal Justice Involvement

- Arrests related to operating under the influence (OUI) have remained stable. It should be noted that Mainers ages 30 to 39 observed a substantial increase in OUI arrests from 2014 to 2018. And for the first time in many years, liquor law violations among youth in Maine increased slightly from 2017 to 2018.
- In 2018, arrests for possession increased slightly to 2,266 and remain stable across substances. Juvenile arrests related to possession have steadily declined from 2014 (409) to 2018 (252).
• In 2019, the majority of Maine Drug Enforcement Agency (MDEA) trafficking investigations involved cocaine, followed by heroin and other opiates. From 2017 to 2019, MDEA trafficking investigations related to heroin have decreased significantly. MDEA investigations involving methamphetamine manufacturing decreased while investigations related to sale increased significantly.

Motor Vehicle Crashes Involving Alcohol/Drugs

• While the number of motor vehicle crashes has increased, the proportion of alcohol and/or drug-related motor vehicle crashes has remained stable at four percent.

• In 2019, Maine drivers ages 21 to 24 had the highest alcohol-related crash rate (359.8 per 100,000 licensees); rates among this age group have shown a slight but steady decrease since 2016.

• In 2019, about one in four (27%) fatal motor vehicle crashes involved alcohol and/or drugs. There was a slight increase in both fatal crashes and non-fatal crashes that involved alcohol and/or drugs.

• In 2017–19, the rate of alcohol/drug-related motor vehicle crash fatalities was highest among 25 to 34-year-olds, followed by 21 to 24-year-olds. This is the first reporting period that 21 to 24-year-olds do not have the highest rate of alcohol/drug-related motor vehicle crash fatalities.

Overdoses and Related Deaths

• In 2019, there were nearly 19,000 alcohol-related ED visits, followed by marijuana related visits (4,583), and opioid (pharmaceutical and illicit) overdose visits (1,214). Regardless of substance type, ED visits for were more prevalent among males compared to females for all substances.

• In 2019, there were a total of 380 overdose deaths due to substance use in Maine. From 2017 to 2018, overdose deaths overall decreased by 15 percent. In 2019, they have increased again by about seven percent and eight out of 10 overdose deaths were related to illicit drugs, while six out of 10 involved a pharmaceutical drug.

• Non-pharmaceutical fentanyl continues to play a major role in drug-related deaths—comprising almost seven out of 10 total deaths—whereas the influence of heroin and benzodiazepines have declined since 2016. However, cocaine, alcohol, benzodiazepines, and heroin respectively, still made up a large proportion of drug-related deaths in 2019.

• Deaths related to alcoholic cirrhosis and liver disease have remained relatively stable among men, increasing from five per 100,000 in 2018 to seven per 100,000 in 2019. Men are twice as likely to experience death related to alcoholic cirrhosis and liver disease compared to women.
**Substance Exposed Infants**

- In 2019, there were 858 notifications to Child Protective Services regarding infants born exposed to substances (drug-affected babies); this accounted for about seven percent of the live births in Maine. After steadily increasing from 2014 to 2016, the number of substance exposed baby notifications began to decline in 2017 and continued to decline by five percent from 2018 to 2019.

**Factors Contributing to Substance Use and Misuse**

**Availability and Accessibility**

- Social access continues to be a primary way that underage youth obtain alcohol. Of those students who obtained alcohol, one in three reported that someone had given it to them.
- In 2019, half of parents did not think that their teen could access alcohol, prescription drugs, tobacco, or marijuana in their home without their knowledge. One-third of parents felt their child could access alcohol at home without permission.
- More than half of high school students believe that marijuana is easy to obtain. This rate has steadily declined from 2009 (58%) to 2017 (52%) and increased by a percentage point in 2019 (53%).
- From 2017 to 2019, the number of prescriptions prescribed for opiate agonists (excluding partial agonists such as buprenorphine) decreased by 18 percent, the number of prescriptions for sedatives decreased by 10 percent, and the count of prescriptions for stimulants increased by 7.5 percent.
- Most calls to Northern New England Poison Center requesting medication verification in 2017–19 involved opioids, followed by benzodiazepines, and stimulants. This continued the trend from the previous reporting period.

**Perceived Harm**

- Four out of five high school students think binge drinking once or twice a week is harmful. Perception of harm from binge drinking remains much lower among young adults. More than seven out of 10 young adults (aged 18 to 25) thought that binge drinking a few times a week was not risky.
- In 2019, about one-third of high school students felt smoking marijuana once or twice a week was risky. In 2017–18, less than one in 10 adults between 18 and 25 years old perceived smoking marijuana at least once per month as risky. Perceptions of harm regarding marijuana use have decreased among both youth and adults over the past several years.
• In 2017–18, about nine out of 10 adults reported that trying heroin once or twice was of moderate-to-great risk. However, youth aged 12 to 17 were much less likely to perceive a risk. Only about one in three 12 to 17-year-olds thought there was great risk from trying heroin once or twice.

**Perceived Enforcement**

• In 2019, half of high school students thought they would be caught by their parents for drinking alcohol, while only about one in five felt they would be caught by the police. Perceptions of getting caught by parents or police have remained stable over the past several years.

• In 2019, less than one quarter of high school students thought they would be caught by police for smoking marijuana. Rates have remained relatively stable over the past several years and decreased by two percentage points from 2017 (24%) to 2019 (22%).

**Community and Cultural Norms**

• High school students largely believe that their parents and adults in their community think it would be wrong for them to drink alcohol regularly. In 2019, more than nine out of 10 students perceived that their parents would think it was wrong for them to use alcohol. Rates have remained stable over the past several years.

• Although high school students generally believe that their parents think it would be wrong for them to smoke marijuana, perceptions of disapproval have slowly decreased from 2009 to 2019; one in five high school students felt their parents would not disapprove.

• In 2019, the most commonly cited reason from parents as to why their teen should not use marijuana was that it was unhealthy (55%); this was followed by potential for addiction (27%), negative impact on child’s future (23%), potential legal problems (18%), teen was too young to use (12%), marijuana use could lead to other substance use (12%), and it was against family values (8%). Two percent of parents surveyed felt it was okay for their teen to use marijuana.

• In 2019, nine in 10 high school students reported that their family has clear rules around alcohol and drug use.

• In 2019, nearly one in 10 (8.2%) parents of 7th thru 12th graders thought their teen had used a vapor product within the past 30 days. One in twenty parents thought their child had used marijuana and four percent believed their teen had drank any alcohol.

• In 2019, high school students who reported three or more adverse childhood experiences (ACEs) reported greater alcohol use, feeling sad or helpless, and serious suicidal consideration when compared to those who reported fewer ACEs.
Mental Health, Suicide and Co-occurring Disorders

Mental Illness, Depression, and Anxiety

- In 2017–18, more than one in five adults in Maine reported experiencing any mental illness in the past year, with adults between 18 and 25 years old experiencing the highest rate (31%). Increases can be observed across all age groups.
- From 2015–16 to 2017–18, the number of 18 to 25-year-olds who experienced at least one major depressive disorder in the past year steadily increased.
- In 2015–17, nearly one in four adults in Maine reported having ever been diagnosed with depression, compared to about one in five reporting to have been diagnosed with anxiety. Adults ages 26 to 35 reported the highest rates of having been diagnosed with anxiety.
- The percentage of Maine high school students who reported feeling sad or helpless for at least two weeks in the past year has steadily increased, from 23 percent in 2011 to 32 percent in 2019; representing an 18.5 percent increase.

Suicidal Ideation

- In 2019, an average of one in seven (16%) Maine high school students seriously considered suicide, and a little more than one in 10 (13%) had planned a suicide; these rates have remained relatively stable. Students who had reported they had attempted suicide decreased from 2015 (10%) to 2017 (7%) and increased to nine percent in 2019.
- In 2019, the percentage of high school students who had consumed alcohol in the past month and also had serious thoughts of suicide within the past year continues to be one in four (26%); this is double the rate compared to students who did not drink.

Mental Health and Substance Use Co-occurrence

- 2-1-1 Maine referral calls increased from 2018 to 2019 for housing/shelter (44.6%), gambling (11%), and mental health (7.8%). Calls for substance use decreased (21%).
- The prevalence of substance use, suicidal ideation, and feelings of sadness and helplessness are higher among high school students who report certain risk factors. Children are much more likely to report feelings of sadness and helplessness if they have not had eight hours or more of sleep, report three or more adverse childhood experiences, or feel that they don’t matter.
Treatment Admissions for Substance Use

Primary Treatment Admissions

- Nearly four in 10 admissions for substance use treatment listed alcohol as the primary reason for treatment in 2018, followed by heroin/morphine, and other opiates/synthetics. In 2018, nearly half (47%) of primary admissions were related to either opioids or opiates, which is consistent with previous years. The proportion of primary admissions related to synthetic opiates continues to decrease as primary admissions involving heroin/morphine continue to increase.

Secondary Treatment Admissions

- Out of the admissions that listed a secondary substance, nearly one in three was related to marijuana and about one in five was related to synthetic opiates. Rates related to synthetic opiates have steadily decreased, while rates involving cocaine/crack have gradually increased.

Treatment Admissions and Pregnant Women

- In 2018, three quarters of primary pregnant substance use treatment admissions were related to opioids/opiates. In recent years, the percentage of pregnant treatment admissions primarily due to other synthetic opioids has steadily declined while the proportion related to heroin has increased.

- The proportion of pregnant women seeking treatment primarily for alcohol has increased steadily in recent years.
Introduction

Demographics of Maine

The state of Maine had an estimated population of 1,344,212 people in 2019. With 21 percent of the population being 65 years old and older, a higher proportion than the overall US population (16%), Maine is considered an “aging” state. Nineteen percent of the state’s population is under the age of 18 years old, a lower proportion than the average for the United States (22%). According to the 2019 U.S. Census estimate, 94.4 percent of Maine’s population is White, non-Hispanic, followed by 1.8 percent who are Hispanic, 1.7 percent who are Black, 1.3 percent who are Asian, and 0.7 percent who are American Indian. There are five Native American tribal communities in Maine: the Penobscot, the Passamaquoddy (Pleasant Point and Indian Township), the Maliseet and the Micmac, but their numbers are likely underreported on the census. Washington, Androscoggin, and Cumberland are the most racially diverse counties, each home to communities made up of people from many ethnic backgrounds and national origins; this is due in large part to refugee resettlement programs located within these counties.

Maine has four metropolitan areas throughout the state, numerous small towns and communities, and vast areas that are virtually unpopulated. While the average number of people per square mile was 43.1 in 2019, this greatly varies by county. The most densely populated counties were Cumberland (with 348 people per square mile) and Androscoggin (with 230.2 persons per square mile), while the least densely populated counties were Piscataquis with 4.4, Aroostook with 10.8, and Washington with 12.8 persons per square mile.

Maine is also an economically diverse state. The median household income was $55,425 for the period of 2014–18, lower than the United States median income of $60,293. This varies greatly by location within the state. The southern coastal counties, such as Cumberland (where most of the population is located) have much higher median incomes than the northern, rural, and less densely populated counties, such as Piscataquis and Washington. At $69,708, Cumberland has the highest median household income, and is one of only three Maine counties where the median income is higher than the national median income (the other two are Sagadahoc at $62,131 and York at $65,538). At the other end of this range, Piscataquis County has the lowest median income of $39,470, while Aroostook County has the second-lowest median income at $39,824 a year.

It is within the context of these demographic and socioeconomic characteristics that substance use in Maine must be examined.
Purpose of this Report

This report considers the primary objectives to identify substance use patterns in defined geographical areas, examine substance use trends, detect emerging substance use, and provide information for policy development and program planning. It also highlights prevention priorities such as underage drinking, high-risk drinking among 18 to 25-year-olds, use of opioids, marijuana use in 12 to 25-year-olds, and slowing the spread of stimulant use; it also monitors the progress being made to address these priorities.

This report includes data through the 2019 calendar year. Older and unchanged data are included when more recent data were not available. Five major types of indicators are included: self-reported substance consumption, consequences related to substance use, factors contributing to substance use, indicators related to mental health and substance use, and treatment admissions. For additional data and resources please visit the Maine State Epidemiological Outcomes Workgroup (SEOW) data dashboard at www.MaineSEOW.com. For more information contact the SEOW Chair, Timothy Diomede at timothy.diomede@maine.gov.

Organization of the Report

Data in this report are often used for assessments, benchmarking and evaluating the progress of outcome measures. This report is also utilized for strategic planning at the local or state-level. Additionally, this data is often used to support applications for funding. Some stakeholders need a snapshot of the status of a substance, while others are looking for longer-term trends. To accommodate these diverse needs, the report is organized as follows:

- The Executive Summary provides the reader with a brief overview of the larger report, including statistics and findings.
- The section Data Sources, Indicators and Selection Criteria describes the data sources and indicators that are included in the profile, as well as the process used to determine which indicators should be included in the profile.
- The Full Report presents the reader with more in-depth comparative and trend analyses for indicators that are critical to substance use and is parsed into five major sections.
  - Consumption trends and patterns among some of the most used substances, to provide the reader a deeper understanding of those substances.
  - Consequences related to substance use, such as traffic accidents and overdoses.
  - Factors that contribute to substance use overall, such as norms and perceptions.
  - Mental Health indicators and how they relate to substance use.
  - Recent trends in substance use treatment admissions.
Data Sources, Indicators and Selection Criteria

This report includes data that were gathered from a multitude of sources. A detailed description of each source is provided below, consisting of information about the data included in each source, the strengths and weaknesses, and retrieval or contact information. This report includes data available through the 2019 calendar year.

A number of criteria are used annually to determine what information should be included in this report. A SEOW workgroup, comprised of data stakeholders, applies these standards to each indicator and selects the best possible data source (or sources) to be included. Indicators that are determined to be redundant, no longer useful, or too confusing are updated to provide the reader with a streamlined and more comprehensive report. Each criterion is defined below:

- **Relevance**: To be included, each of the indicators must be directly related to substance use. The indirect effects of substance use reach throughout society in such areas as crime, health and education. However, this report limits indicators to those which can be directly related to substance use (e.g., ambulance responses in which substance use was recorded as a factor, rather than generating an estimate of the percentage of all responses that could be related to substance use).

- **Timeliness**: Each of the indicators includes the most updated data available from the source. The timeliest data included are from the previous six months or year, but some data as old as three years may be included. This happens when the most recently collected data from the source are not yet available due to the timing of data collection and the publication of this report. The sources that reflect older information are included when they meet other important criteria. For example, the National Survey on Drug Use and Health, for which the most recent data available are from 2017–18, provides data that are highly relevant and reliable.

- **Availability**: For an indicator to be included in this report, data regarding its use must be available from a reliable source. That is, a question must be asked on a representative survey or an office must record incidents, and the source must be willing to release the results either to the general population, or the SEOW and/or its members. As stated above, the most recent data available from those sources are included in this report.

- **Reliability**: In order to include trended data in this report, the data available for each indicator must be reliable and comparable from year to year. They need to reflect the same indicator in the same manner for the same population each year. Where this is not possible, new indicators are updated and the baseline year is established.
• **Trending:** Trends are included in this survey for indicators in which reliable and comparable data are available from multiple years. In some instances, trending is limited or not possible due to limited availability of the data, changes in the way in which the data were collected, or changes in the survey question. For example, questions regarding the use of specific substances have been included and discontinued in surveys as those substances have become more or less of a concern. Therefore, trending is only available for their use in the years those questions were included in the survey.

As described previously, there are multiple purposes for this report. One is to provide a snapshot of the most recent data regarding substance use, while another is to examine trends over time. Therefore, each indicator may have multiple sources of data that are included. While each indicator provides a unique and important perspective on substance use in Maine, none should individually be interpreted as providing a full picture of trends related to substance use in Maine. We caution data users not to rely heavily on a single indicator in their assessment and evaluation; instead, we structure and present resources within a larger context to help users look at the broader picture. That is to say, the percentages and figures from one data source do not always align with the data and percentages from a similar source.

Older data are often included to examine an indicator among a specific population or to identify trends over time. Substance use prevention strategies are successful when conducted over a long period and data monitoring should reflect this process. When discussing rates of prevalence, however, the user should rely upon the most recent data source available. We promote the use of data indicators that have the reputation of being accurate, reliable, and timely.

**Description of Data Sources**

**Behavioral Risk Factor Surveillance System (BRFSS).** The BRFSS is a national survey administered on an ongoing basis by the National Centers for Disease Control and Prevention (CDC) to adults in all 50 states, several districts and territories. The instrument collects data on adult risk behaviors, including alcohol and drug use. The most recent data available are from 2017. **2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.** Due to methodological changes in weighting and sampling, data prior to 2011 cannot be trended with more current data. In some instances, due to smaller sample sizes, multiple years of data are combined in efforts to produce more reliable estimates. **Contact:** Melissa Damren, Maine BRFSS Coordinator; [melissa.damren@maine.gov](mailto:melissa.damren@maine.gov); (207) 287-1420.

**Maine Department of Public Safety (DPS), Bureau of Highway Safety (BHS), Maine Department of Transportation (MDOT).** The Bureau of Highway Safety is responsible for tracking all fatalities that occur on Maine's highways and reporting this information through the Fatal Analysis Reporting System (FARS). The data represented provide information on highway crashes and fatalities. Much of this information is gathered from the FARS system, which records data on fatal crashes in Maine for input into a larger national record-keeping system of statistical data. FARS data are also used by BHS and the Maine State Police to analyze enforcement priorities and schedules. Impaired driving is one of the most serious traffic risks facing the nation, killing
thousands every year. **Contact:** For FARS data/fatal crashes, contact Lauren Stewart, Highway Safety Director; [lauren.v.stewart@maine.gov](mailto:lauren.v.stewart@maine.gov); (207) 626-3841. For all other crash data, contact the Maine DOT; (207) 624-3000.

**Maine Department of Public Safety (DPS), Uniform Crime Reports (UCR).** UCR data include drug and alcohol arrests. Drug arrests include sale and manufacturing as well as possession of illegal substances. Liquor arrests include all liquor law violations. OUI arrests are arrests for operating a motor vehicle under the influence of a controlled substance. DPS data are now available from 2017. Arrest data may reflect differences in resources or focus of law enforcement efforts, so may not be directly comparable from year to year. Available at: [http://www.maine.gov/dps/cim/crime_in_maine/cim.htm](http://www.maine.gov/dps/cim/crime_in_maine/cim.htm).

For UCR statistical purposes, “arrests” also include those persons cited or summoned for criminal acts in lieu of actual physical custody. These forms categorize the arrests by offense classification (both Part I and Part II crimes), and by age, sex and race. The same individual may be arrested several times over a period of time; each separate arrest is counted. A person may be arrested on several charges at one time; only one arrest is counted and is listed under the most serious charge. For UCR purposes, a juvenile is counted as “arrested” when the circumstances are such that if he or she were an adult, an arrest would result; in fact, there may not have been a formal charge.

**Maine Drug Enforcement Agency (MDEA).** The MDEA through its regional multi-jurisdictional task forces is the lead state agency in confronting drug trafficking crime. The data included in this report represent those arrested for a drug offense but do not indicate what other drug(s) may have been seized. For example, a person may be arrested for the sale of cocaine but also be in possession of oxycodone and marijuana. It is important to note that arrests and multi-jurisdictional drug enforcement are resource-dependent; such funds fluctuate from year to year and must be reallocated to combat highest-priority threats. **Contact:** Roy E. McKinney, Director; [roy.e.mckinney@maine.gov](mailto:roy.e.mckinney@maine.gov); (207) 626-3852.

**Maine Emergency Medical Services (EMS).** Maine EMS is a bureau within the Maine Department of Public Safety (DPS) and is responsible for the coordination and integration of all state activities concerning Emergency Medical Services and the overall planning, evaluation, coordination, facilitation and regulation of EMS systems. EMS collects data statewide from the 272 licensed ambulance and non-transporting services. It is mandated that services submit an electronic patient care report to Maine EMS within one business day of patient contact. Data are compiled upon request. Beginning in March of 2017, Maine EMS began a transition from the NEMSIS version 2 data set to the NEMSIS version 3 data set. Among other things, this transition afforded Maine EMS clinicians the ability to document a broader range of diagnoses, as seen with the alcohol-related data. **Contact:** Darren Davis, Maine Emergency Medical Services; [Darren.W.Davis@maine.gov](mailto:Darren.W.Davis@maine.gov); (207) 626-3860.
**Maine Integrated Youth Health Survey (MIYHS).** The MIYHS is a statewide survey administered biennially since 2009 through a collaborative partnership between Maine Department of Health and Human Services and Maine Department of Education. Its purpose is to quantify health-related behaviors and attitudes of 5th through 12th graders by direct student survey. The survey collects information on student substance use, risk factors related to substance use, as well as consequences, perceptions and social risk factors related to substances, and information on many other health factors. MIYHS defines binge-drinking as consuming five or more drinks in a row. As of the date of this report, the most recent data available are from 2019. **Contact:** Korey Pow, Center for Disease Control and Prevention; korey.pow@maine.gov; (207) 287-5084.

**Maine Office of the Chief Medical Examiner.** The Maine Office of the Chief Medical Examiner investigates all deaths associated with drug overdose. Analysis of these cases is currently funded by the Office of Attorney General. The death data are reported on a quarterly and an annual basis after cases are finalized; they are released through the Attorney General’s Office. Drug categories reported to SEOW include methadone, cocaine, benzodiazepines, oxycodone, fentanyl, and heroin/morphine. **Contact:** Dr. Marcella Sorg, Director, Rural Drug & Alcohol Research Program, Margaret Chase Smith Policy Center, University of Maine; mhsorg@maine.edu.

**National Survey on Drug Use and Health (NSDUH).** The NSDUH is a national survey administered annually by the Substance Abuse and Mental Health Services Administration (SAMHSA) to youth grades 6 through 12 and adults ages 18 and older. The instrument collects information on substance use and health at the national, regional and state levels. The advantage of NSDUH is that it allows comparisons to be made across the lifespan (that is, ages 12 and up). However, NSDUH is not as current as other data sources; as of this report, data at the state level are available from 2017–18.

Older data are included for trending and comparative purposes. In 2016, several changes were made to the NSDUH questionnaire and data collection procedures, resulting in the establishment of a new baseline for many measures. Therefore, estimates for several measures included in prior reports are not available. For details, see Section A of SAMHSA’s “2015–2016 National Survey on Drug Use and Health: Guide to State Tables and Summary of Small Area Estimation Methodology” at https://www.samhsa.gov/data/report/2015-2016-nsduhguide-state-tables-and-summary-sae-methodology.

NSDUH defines “Illicit Drugs” as marijuana/hashish, cocaine (including crack), heroin, hallucinogens, inhalants, or any prescription-type psychotherapeutic used non-medically; “Binge Alcohol Use” as drinking five or more drinks on the same occasion (i.e., at the same time or within a couple of hours of each other) on at least one day in the past 30 days; “Dependence” or “Abuse” based on definitions found in the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-V); and “Serious Mental Illness” (SMI) as a diagnosable mental, behavioral, or emotional disorder that met the criteria found in the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-V) and resulted in functional impairment that substantially interfered with or limited one or more major life activities. Available at:
Northern New England Poison Center (NNEPC). The Northern New England Poison Center provides services to Maine, New Hampshire, and Vermont. A poisoning case represents a single individual’s contact with a potentially toxic substance. Intentional poisoning includes those related to substance use, suicide and misuse. Data include the number of confirmed cases where exposures are judged to be substance use-related (i.e., an individual's attempt to get high). NNEPC collects detailed data on specific substances involved in poisonings, including the categories of stimulants/street drugs, alcohol, opioids, asthma/cold and cough medications, benzodiazepines, antidepressants, and pharmaceuticals, as well as other substances. The category of stimulants/street drugs includes marijuana and other cannabis, amphetamine and amphetamine-like substances, cocaine (including salt and crack), amphetamine/dextroamphetamine, caffeine tablets/capsules, ecstasy, methamphetamine, GHB, and other/unknown stimulants/street drugs. The category alcohol includes alcohol-containing products such as mouthwash. The opioid category includes Oxycodone, Hydrocodone, buprenorphine, methadone, tramadol, morphine, propoxyphene, codeine, hydromorphone, stomach opioids, Meperidine (Demerol), heroin, Fentanyl, and other/unknown opioids. Data available from the poison center are reported on a continual daily basis and are included through December 2018. These data are only reflective of cases in which the Poison Center was contacted. Contact: Colin Smith, Northern New England Poison Center; SMITHC12@mmc.org; (207) 662-7085.

Data, Research and Vital Statistics (DRVS). DRVS is an office within the Maine CDC. Death certificates are the source documents for the data on the vital events in Maine. The data include either all deaths occurring in Maine or only deaths to Maine residents depending upon the indicator. Based on death certificate database ICD-10 codes for alcohol or drug related deaths. Data include unintentional, self-inflicted, assault and undetermined intent deaths. Contact: Anne Rogers, Data, Research and Vital Statistics; anne.rogers@maine.gov; (207) 287-5468.

Parent Survey. In 2006, the Maine Office of Substance Abuse and Mental Health Services (SAMHS) commissioned Pan Atlantic Research, a Maine-based marketing research and consulting firm, to conduct baseline quantitative market research with parents of teenagers throughout the state on a range of issues related to underage drinking. The 2006 research was a component of a broader project being conducted in preparation for a social marketing campaign aimed at parents, the objective of which was to reduce teenage drinking in the State of Maine through improved parenting techniques and enhanced parental involvement.
Pan Atlantic Research has subsequently conducted benchmarking research on this project for SAMHS and the Maine Center for Disease and Control in 2007, 2008, 2009, 2011, 2013, 2015, 2017 and most recently in 2019. In 2008, many changes were made to better align with/reflect existing surveys and the state’s public health service infrastructure. These include research designed to be more directly comparable to the 2009 (and future) Maine Integrated Youth Health Surveys (MIYHS), the sample being stratified on a statewide basis according to Maine’s eight Public Health Districts (150 completed surveys per PHD), and the sample composition including parents of 7th to 12th graders (200 per grade, for 1,200 total). The survey was redesigned in 2019 to increase its emphasis on questions relating to teenage use of marijuana and prescription drugs. **Contact:** Jason Edes, Director of Research, Pan Atlantic Research; jedes@panatlanticresearch.com; (207) 221-8877 ext. 100.

**Pregnancy Risk Assessment Monitoring System (PRAMS).** PRAMS is an ongoing, population-based surveillance system designed to identify and monitor selected maternal behaviors and experiences before, during, and after pregnancy among women who have recently given birth to a live infant. Data are collected monthly from women using a mail/telephone survey. **Contact:** Virginia Buchanan, PRAMS Coordinator, Maine CDC; Virginia.Buchanan@maine.gov; (207) 287-5469.

**Prescription Monitoring Program (PMP).** PMP maintains a database of all transactions for class C–II through C–IV drugs dispensed in the state of Maine. Drug categories used in this report include opiates, sedatives, and stimulants. The counts included in this report represent the number of prescriptions and doses dispensed between 2016 and 2018. **Contact:** Office of Substance Abuse and Mental Health Services; SAMHS.PMP@maine.gov; (207) 287-2595.

**Syndromic Surveillance System.** Maine’s hospital syndromic surveillance system collects information from hospital emergency departments and, in some cases, their affiliated urgent care centers. Maine CDC has 33 hospital emergency departments participating in syndromic surveillance reporting approximately 2000 ED visits per day (depending on the time of year and other factors that affect patient traffic). Maine CDC is constantly working to improve the system, so data are subject to change as additional facilities/data fields/facility types are added. ED visits are based on patient residence. The Maine Syndromic Dashboard can be found here: https://www.maine.gov/dhhs/mecdc/infectious-disease/epi/syndromic/index.shtml. **Contact:** Maine CDC; syndromic@maine.gov.

**Web Infrastructure for Treatment Services (WITS).** WITS does not capture data from all treatment facilities or services provided in Maine and therefore is not a complete representation of ALL substance use treatment services provided in Maine. WITS is the State system that all licensed substance use treatment agencies are required by licensing rule to submit all substance use treatment services rendered into. However, there are many organizations and private practitioners, such as primary care practitioners and independent substance use licensed counselors, who are not mandated to enter data into the system. Analyses in this report are based on client-reported primary, secondary and tertiary drug(s) of choice, as well as other demographic and background information that is collected at intake. It is important to note that
the WITS system is not static; therefore, 2017 numbers may be artificially low. Drug categories included in this report are alcohol, marijuana, cocaine, heroin, synthetic opiates, methadone/buprenorphine and benzodiazepines. Contact: Office of Behavioral Health; TDS.Helpdesk@maine.gov; (207) 287-2595.

2-1-1 Maine. 2-1-1 Maine is a free, confidential resource for individuals to connect to thousands of health and human services in Maine. 2-1-1 Maine maintains a statewide directory of resources including services for substance use, mental health, gambling addiction, housing, childcare and more. Individuals can contact 2-1-1 Maine and access needed information and referrals by calling 2-1-1 and speaking with a trained specialist in Maine, by texting their ZIP code to 898-211 and communicating with a Maine-based specialist, or by visiting www.211maine.org. 2-1-1 Maine’s Contact Center operates 24 hours a day, seven days a week, 365 days a year. 2-1-1 Maine is a collaborative effort of the Maine Department of Health and Human Services, the United Ways of Maine, and The Opportunity Alliance as the Contact Center partner. Contact: info@211maine.org; call 2-1-1 or 1-866-811-5695; text your ZIP code to 898-211.

Consumption of Substances

Consumption and misuse of alcohol, cigarettes, marijuana, prescription and other drugs can have detrimental effects on an individual’s well-being, including increased risks of morbidity, addiction, chronic diseases, and mortality. In addition, substance use can have a harmful impact on society, including motor vehicle accidents, crime, straining health/medical resources, and lowering work productivity. It is the manner and frequency with which people use drugs and/or alcohol that are often linked to substance-related consequences.

To understand the magnitude of substance use consequences, it is important to first measure the prevalence of substance consumption itself. Consumption includes overall use of substances, any use (ever/lifetime and in the past month), heavy consumption (such as binge drinking), and consumption by high-risk groups (e.g., youth, young adults, pregnant women). Monitoring substance use is more relevant during the COVID-19 pandemic than ever. Effective and timely data collection helps the state of Maine to be proactive rather than reactive in this unprecedented situation. The SEOW will track substance use changes in the coming years to determine the impact this pandemic has had and will have on Mainers.

Alcohol continues to be the substance most often used by Mainers across the lifespan, but especially in youth and young adults. Risky alcohol use, such as binge or high-risk drinking, remains a concern among adults 18 to 35, with nearly one in three reporting such behavior in the past month. Alcohol use among Maine’s high school students has slowly declined since 2011; however, one-third of students who drank in the past month reported high-risk alcohol use (defined as having five or more drinks in a row) at least once in the past month. The most concerning high-risk drinking rates in the adult population can be observed among 18 to 24-year-olds and 25 to 34-year-olds, with about one in three reporting high risk drinking within the past month. Two out of five underage adults (18 to 20-year-olds) reported having a drink in the past month, which has remained consistent for the past several years. To combat improper alcohol use, there are a variety of programs at the state and community level aimed at reducing risky alcohol behaviors among adults as well as youth.

Although alcohol poses a great risk to many Mainers, it is important to remember that cigarettes, marijuana, vapor products, and prescription drugs are also commonly used substances in Maine. The majority of parents reported that they believe their children are honest with their consumption of substances, but there continues to be a gap between self-reported use and parental perception. Youth are continuing to use more often than parents appear to know.

In terms of tobacco use, about one in four Mainers between 25 and 44 years old reported currently smoking cigarettes, compared to fewer than one in seven adults aged 18 to 25; rates of tobacco use have progressively declined among youth and young adults in Maine but remain somewhat consistent among older age groups. Tobacco use among pregnant women, while still a concern, is decreasing slightly; roughly one in eight reported using cigarettes in their last trimester. Tobacco use is becoming less common in the younger generations but is being replaced by alternatives.
Since emerging as an alternative form of smoking, vapor products have overtaken cigarettes as a preferred form of consumption for high school students. In 2019, nearly half of high schoolers reported using an electronic vapor product in their lifetime. Approximately three out of 10 high school students have used a vapor product in the past month. These rates have doubled since 2017. In 2019, high school students who reported ever using a vapor product most commonly reported the liquid/product they last used included nicotine, which is much different from 2017 when more than half reported vaping just flavoring. In 2019, about one in four believe they were vaping just flavoring and about one in eight were vaping marijuana; seven percent were not sure what kind of liquid was in the vapor product they used. In addition, 40 percent of high school students reported borrowing the vapor product from a friend instead of procuring their own.

Nationally and statewide, efforts are being made to remove appealing flavors and packaging from vapor products to deter youth from using them. There is a need to intervene with youth who are regularly using vapor products as increasing number of youth are reporting use. As for adults, all age groups saw an increase in the rate of those using e-cigarettes from 2016 to 2017. In 2017, the number of Mainers using e-cigarettes surpassed those smoking cigarettes. One positive finding is that only a small group of pregnant women report using an e-cigarette in the last trimester of their pregnancy.

Adult use marijuana was legalized in Maine beginning in 2016. Marijuana use among young adult Mainers, as well as use by those 26 and older, has been steadily increasing over the past several years. The 18 to 25-year old population reported using marijuana more than any other age group. More than one in three young adults (18 to 25-year-olds) and one in six residents 26 years and older reported use within the past month. There was an increase in the number of individuals 18 to 25 who initiated use and an even larger increase in the number of individuals 26 years and older who initiated use, which indicates that all ages are at risk. Another population who reports using marijuana more and more are women in their third trimester of pregnancy; one in eight reported using marijuana during their third trimester in 2019.

In recent years, past-year and past-month rates of prescription drug misuse among youth and adults have remained relatively stable. Seven percent of 18 to 25-year-olds reported having misused pain relievers in the past year while four percent of adults 26 and older reported misusing pain relievers in the same period. Additionally, approximately one in 10 adults between the ages of 26 and 35 reported misuse of any type of prescription drug at least once in their lifetime. According to the 2019 Maine Integrated Youth Health Survey, reported lifetime heroin use in high school students remains low. In 2016–17, The National Survey on Drug Use and Health reported that less than one percent of Mainers aged 12 and older reported that they had used heroin in the past year, with use highest use among young adults between 18 and 25 years old.
Finally, cocaine use rates among Mainers aged 18 to 25 have increased from 2013–14 to 2017–18, while rates of use among adults 26 and older have remained relatively stable. In recent years the lifetime rates of high school students using cocaine or methamphetamine have remained stable. It is important that we continue to monitor rates of stimulant drug use closely. According to recent public health surveillance data, methamphetamine, cocaine, and other potentially addictive and dangerous prescription drug stimulants are emerging concerns that deserve immediate attention in Maine.
**Alcohol: Current Use Among Youth**

**Indicator Description:** This measure shows the percentage of high school students who reported having had one or more alcoholic drinks on one or more days within the past month.

**Why Indicator is Important:** Alcohol is the most often-used substance among youth in Maine. While alcohol consumption carries risk for adults, developing adolescent brains are especially susceptible to the health risks of alcohol consumption. Adolescents who consume alcohol are more likely to have poor grades and be at risk for experiencing social problems, depression, suicidal thoughts, assault, and violence.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** Less than one-quarter of high school students reported consuming alcohol in the past month in 2019. The rate of alcohol consumption decreased steadily from 2011 to 2017 but has stayed consistent from 2017 to 2019.

![Figure 1. High school students reporting alcohol use in the past month: 2011–2019](image)

- The rate of high school students consuming alcohol in the past month decreased by five percentage points, from 28 percent in 2011 to 23 percent in 2019.
- Although not shown, more than one-third of high school students who have ever consumed alcohol reported that someone gave them the alcohol as opposed to purchasing or stealing it from a store.
**Alcohol: Current High-Risk Use Among Youth**

**Indicator Description:** This indicator displays the percentage of youth who reported having had five or more alcoholic drinks within a couple of hours in the past month. In 2019, the MIYHS redesigned the question asked of students regarding the frequency of high-risk alcohol use. Therefore, 2019 data cannot be compared to previous years for trending purposes.

**Why Indicator is Important:** Youth are more likely to engage in high-risk use than adults when they consume alcohol. High-risk alcohol use contributes to violence and motor vehicle crashes and can result in negative health consequences for the consumer, including injury and chronic liver disease. Youth who engage in high-risk drinking are also more likely to use other substances and engage in risky behavior.

**Data Source(s):** MIYHS, 2019

**Summary:** In 2019, among high school students who reported drinking in the past month, one third reported they had five or more drinks over the period of a couple hours at least once in the past month. Although not shown, this accounts for roughly eight percent of all high school students. Females are less likely than their male counterparts to participate in this behavior, as are younger students relative to older students.

![Figure 2. High school students (among those who reported drinking in the past month) who had five or more drinks in a row at least once in the past month: 2019](image)

*Source: MIYHS, 2019*

- Twelfth grade students were most likely to report that they had engaged in high-risk alcohol use within the past month when compared to the other high school grades.
**Alcohol: Current Use Among Underage Adults**

**Indicator Description:** This indicator portrays the alcohol use patterns among adults between the ages of 18 and 20; specifically, those who reported consuming any alcohol in the past month.

**Why Indicator is Important:** Alcohol is one of the most often-used substances by underage adults in Maine. Excessive and high-risk alcohol use may contribute to violence and result in many negative health consequences for the consumer. Drinking alcohol can also have negative health effects and lead to such consequences as alcohol-related motor vehicle crashes and increased injuries.

**Data Source(s):** BRFSS, 2013–15 to 2015–17

**Summary:** Among adults 18 to 20 years of age, about two in five reported consuming any alcohol in the past month; rates have remained steady from 2013–15 to 2016–17. High-risk alcohol use rates have decreased slightly over the same time frame, with about one in five reporting such use in the past month.

![Figure 3. Adults ages 18 to 20 reporting drinking in past 30 days by type of drinking: 2013–15 to 2015–17](image)

*Source: BRFSS, 2013–15 to 2015–17*

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.

- During the 2015–17 period, among Mainers between 18 and 20 years old, 40 percent reported consuming any alcohol in the past 30 days, 20 percent reported binge drinking, and eight percent were at risk from heavy alcohol use.
**Alcohol: At Risk of Heavy Use**

**Indicator Description:** This indicator examines the percentage of Maine residents who are at risk of suffering consequences from heavy drinking in the past month. “At risk of heavy drinking” is defined as more than two drinks per day (14 per week) for a man or more than one drink per day for a woman (seven per week).

**Why Indicator is Important:** People who consume alcohol frequently are at increased risk for a variety of negative health consequences, including alcohol use and dependence, liver disease, certain cancers, pancreatitis, heart disease, and death. It has also been found that the more heavily a person drinks the greater the potential for problems at home, work, and with friends.¹

**Data Source(s):** BRFSS, 2014–15 to 2016–17

**Summary:** Risk of heavy alcohol use among 18 to 25-year-olds has remained stable from 2014–15 to 2016–17. However, the risk for heavy use among all other age groups has increased slightly in the same time period.

![Figure 4. Adults at risk of heavy alcohol use in past 30 days, by age group: 2014–15 to 2016–17](image)

*Source: BRFSS, 2014–15 to 2016–17*

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.

- During the period 2016–17, nine percent of adults 18 and over reported having consumed alcohol daily, putting them at risk from heavy alcohol use.

Alcohol: Current High-Risk Use Among Adults

Indicator Description: This indicator reflects the percentage of adults who reported consuming several alcoholic beverages in a row for at least one day within the past month. ²

Why Indicator is Important: Binge drinking is a type of high-risk drinking, meaning it increases the risk for many health- and social-related consequences. High-risk alcohol use has been linked to injury (such as falls, fights, and suicides), violence, crime rates, motor vehicle crashes, stroke, chronic liver disease, addiction, and some types of cancer.

Data Source(s): BRFSS, 2016 to 2018

Summary: The highest binge drinking rates can be observed among 18 to 24-year-olds and 25 to 34-year-olds, with about one in three reporting high risk drinking within the past month. While rates among most age groups have remained relatively stable or decreased, rates for 18 to 24-year-olds have observed an increase from 2017 to 2018.

Figure 5. Adults reporting high-risk drinking in past 30 days, by age group: 2016 to 2018*

Source: BRFSS, 2016 to 2018

² BRFSS defines binge drinking (high-risk drinking) as five or more drinks in one sitting for a male and four or more drinks in one sitting for a female.
Tobacco and Vaping Product Use: *Cigarette, Cigars, and Smokeless Tobacco Use Among Youth*

**Indicator Description:** This indicator illustrates the percentage of youth who reported using cigarettes, cigars, and smokeless tobacco within the past month.

**Why Indicator is Important:** Use of tobacco is associated with greater risk of negative health outcomes, including cancer, cardiovascular, chronic respiratory diseases, and can lead to death.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, fewer than one in 10 students reported having smoked a cigarette within the past month. The use of tobacco products among high school students continues to steadily decline.

![Figure 6. High school students who used tobacco during past month, by tobacco type: 2011–2019](image)

*Source: MIYHS, 2011 to 2019*

- The percentage of high school students who reported having smoked any cigarettes on at least one day during the past 30 days decreased by nine percentage points from 2011 (16%) to 2019 (7%).
- Although not shown, among students who reported current cigarette use in 2019, nine percent reported smoking more than 10 cigarettes per day. This is a decrease of three percentage points from 2017. Among students who have ever smoked an entire cigarette, 55 percent reported having done so before age 13.
- The only tobacco type that saw an increase in use from 2017 to 2019 was cigars. The rates of smokeless tobacco and cigarette use have both decreased from 2017.
**Tobacco and Vaping Product Use: Vaping Use Among Youth**

**Indicator Description:** This indicator illustrates the percentage of youth who reported using vapor products (*e.g.*, electronic cigarettes, vaporizers). Questions about vapor products were added to the survey in 2015.

**Why Indicator is Important:** Vapor products have become a popular alternative to smoking cigarettes as they have been marketed as safer than normal cigarettes. These products are often marketed to youth through appealing flavors and bright colors. There is a growing amount of research that suggests electronic vapor products may not be a safe alternative to traditional tobacco products and can also contribute to respiratory problems. Vitamin E acetate is an additive to vaping products – Vitamin E is commonly found in foods and other topical products. Research shows that when Vitamin E acetate is inhaled, it can interfere with normal lung functioning.

The FDA has become aware that some people who use e-cigarettes have experienced seizures, with most reports involving youth or young adult users.³ Many e-cigarettes come in fruit, candy, and other kid-friendly flavors, such as mango, fruit and crème. Youth reported using e-cigarettes because they are curious about these new products, and because they believe these products to be less harmful than conventional cigarettes.⁴ The CDC and FDA recommend that vaping products not be acquired from informal sources such as friends, family or online dealers, but more importantly vaping products should never be used by youths, young adults or women who are pregnant.⁵

**Data Source(s):** MIYHS, 2011–2019

**Summary:** Nearly half of all high school students reported having ever used a vaping product and almost one third reported using in the past month. Among students who had ever used a vaping product, more than half reported that the last time they vaped it had nicotine, a quarter reported it was flavored, one in eight reported it was Marijuana-based oil, and seven percent were unsure what was in the vapor. Past-month use of vapor products increased notably, nearly doubling from 2017 to 2019.

---

Figure 7. High school students who used an electronic vapor product* in the past 30 days or lifetime: 2015–2019

Source: MIYHS, 2015 to 2019

*Electronic vapor products refer to devices used to vaporize active ingredients of plant material, commonly tobacco, cannabis, or herbs for the purpose of inhalation.

- Nearly half of high school students reported having ever used an electronic vaping product in 2019. This is a substantial increase from 2017. The rate of past-month use nearly doubled from 2017 to 2019 with nearly one-third of high schoolers reporting using an electronic vapor product in 2019.

Figure 8. Type of vapor product used by high school students (among those who reported ever using): 2017 and 2019

Source: MIYHS, 2017 to 2019
• In 2019, high school students who reported ever using a vapor product most commonly reported the liquid/product they last used included nicotine. This is much different from 2017 when 54 percent reported vaping just flavoring. In 2019, about one in four believe they were vaping just flavoring, and about one in eight were vaping marijuana (13%). Seven percent were not sure what kind of liquid was in the vapor product they used.

• Although not pictured, most high school students who used a vapor product reported that they obtained it by borrowing it from someone else (40%). Only about five percent of those who used a vapor product bought it from a convenience store themselves.
Tobacco and Vaping Product Use: Cigarette Use Among Adults

Indicator Description: This indicator depicts cigarette use among adults who reported smoking at least 100 cigarettes in their lifetime and currently smoke cigarettes either every day or every couple of days.

Why Indicator is Important: Tobacco use has been linked to several negative health outcomes, including cancer, cardiovascular, chronic respiratory diseases, and can lead to death. Second-hand smoke is also associated with many negative health outcomes, such as increased colds, flu, asthma, bronchitis, lung cancer, and low birth weight babies.

Data Source(s): BRFSS, 2016 to 2018

Summary: There has been a decrease in young adults 18 through 34 years of age who report being current smokers. Adults 55 and older have steadier rates of current cigarette use with those 65 and older seeing a slight increase from 2017 to 2018.

Figure 9. Current cigarette use among adults, by age group: 2016 to 2018

Source: BRFSS, 2016 to 2018

- In 2018, the age group with the greatest prevalence of current cigarette smokers were those 25 to 44 years old, of whom 26 percent reporting being current smokers. Adults aged 45 to 54 (21%) reported the next-highest rate of current smokers, compared to 55 to 64-year-olds (18%), 18 to 24-year-olds (14%), and Mainers 65 and older (9%).
Tobacco and Vapor Use: E-Cigarette Use Among Adults

Indicator Description: This indicator depicts current electronic or e-cigarette use among adults.

Why Indicator is Important: While often portrayed as a safer form of smoking, use of electronic cigarettes is also associated with negative health outcomes, like nicotine addiction and lung disease. E-cigarettes are not safe for adults who do not currently use tobacco products. Vitamin E acetate is strongly linked to an e-cigarette or vaping use-associated lung injury (EVALI) outbreak. Vitamin E acetate has been found in product samples tested by FDA and state laboratories and in-patient lung fluid samples tested by CDC from geographically diverse states. Vitamin E acetate has not been found in the lung fluid of people that do not have EVALI. More research is underway on this issue.

Data Source(s): BRFSS, 2016–2017

Summary: In 2017, approximately one in five Mainers 18 and older reported current use of e-cigarettes. Use of electronic cigarettes increased slightly for every age group between 2016 and 2017. However, this increase in e-cigarette use appears to correlate to a decrease in traditional cigarette smoking during the same time period.

Figure 10. Current e-cigarette use among adults, by age group:
2016–2017*  

Source: BRFSS, 2016 to 2017  

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.

---

In 2017, 21 percent of Maine adults reported being current e-cigarette smokers. Mainers between 18 and 25 years old reported the highest rate of e-cigarette use, at 23 percent.

Figure 11. Current adult e-cigarette and cigarette usage, by type: 2016–2017*

Source: BRFSS, 2016 to 2017

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.

Similar to high school student usage of vapor products, electronic cigarettes are also increasing in popularity among adults over traditional cigarettes.
Marijuana: Current Marijuana Use

Indicator Description: This measure shows the percentage of Mainers who reported using marijuana in the past month. This is presented for high school students and across the lifespan (i.e., among Mainers over the age of 12).

Why Indicator is Important: Marijuana can be addictive and is associated with increased risk for respiratory illnesses and memory impairment. Also, youth who begin smoking marijuana at an early age are more likely to develop a substance use disorder and dependence later in life. State-level marijuana liberalization policies have been evolving for the past five decades, and yet the overall scientific evidence of the impact of these policies is widely believed to be inconclusive. Many US states have moved away from a strict prohibition position toward marijuana well before considering outright legalization. There are a variety of ways to consume marijuana, with the most common methods including smoking, vaporization, and ingestion of edible products, as well as new techniques for controlling potency. Legalization will broaden access to these new products to even more users. It is difficult to predict the extent to which legalization will increase product innovation, as growth in the industry will promote the development of new methods for extracting and synthesizing the byproducts of the cannabis plant.

Summary: From 2017 to 2019, a three-percentage point increase in past-month marijuana use was observed among high school students. More than one in five high school students reported using marijuana within the past month. Two out of three students who reported using marijuana, reported usually smoking it while a little more than one in 10 (12% said they vaporized it. The highest rates of marijuana use among adults continues to be observed among 18 to 25-year-olds (35%). Marijuana use rates among adult Mainers have been steadily increasing over the past several years.

---

The percentage of high school students who reported using marijuana one or more times during the past month stayed relatively consistent from 2011 (22%) to 2019 (22%). Although not explicitly shown, according to the 2019 Parent Survey, only five percent of parents of middle school and high school students believed their child had used marijuana in the past 30 days.

* Dabs are cannabis concentrates gaining notoriety for their significant amounts of tetrahydrocannabinol (THC) that are ultimately vaporized and inhaled for their effect.10

---

In 2019, among high school students who reported using marijuana within the past month, two thirds (66%) reported that they had most often smoked marijuana in either a joint, bong, or blunt; this was followed by administration through an electronic vapor product (12%), dabbing it using waxes or concentrates (9%), consumption through edibles (8%), drinking it (3%), and some other way (2%).

Source: NSDUH, 2013–14 to 2017–18

Of Maine residents between 18 and 25 years of age, 35 percent reported using marijuana in the past month in 2017–18; this is an increase of seven percentage points since 2013–14. Marijuana use rates among those aged 26 and older increased by four percentage points, from 11 to 15 percent, in same time period.
In 2017, 16 percent of Maine adults (18 and older) reported using marijuana within the past 30 days. The highest rates were observed among 18 to 25-year-olds and 26 to 35-year-olds, at 31 percent.

Source: BRFSS, 2017

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.
Marijuana: *Initiation of Marijuana Use*

**Indicator Description:** This measure shows the average number of Mainers that used marijuana for the first time in their life in a specific period of time. Average annual number of marijuana initiates = \( X_1 \div 2 \), where \( X_1 \) is the number of marijuana initiates in the past 24 months.

**Why Indicator is Important:** Marijuana can be addictive and is associated with increased risk for respiratory illnesses and memory impairment. Youth who begin smoking marijuana at an early age are more likely to develop substance use and dependence later in life.\(^\text{12}\) Marijuana is the most widely used drug among adolescents. It can be addictive and is associated with increased risk for respiratory illnesses and memory impairment. In addition to the risk of developing a marijuana use disorder (MUD) and using other illegal substances, research has indicated significant associations between adolescent marijuana use and poor social and educational development and functioning, as well as having other mental health problems. In addition, adverse consequences of marijuana use can extend into adulthood, including substance use and misuse, cognitive impairment, criminal justice involvement, and ongoing mental and physical health problems.

**Data Source(s):** NSDUH, 2015–16 to 2017–18

**Summary:** About 19,000 Mainers 12 years and older reported using marijuana for the first time in their life in 2017–18. Five thousand initiates were between 12 and 17; 7,000 were between 18 and 25; and another 7,000 initiates were 26 and older. The number of initiates 26 and older more than doubled from 2016–17 to 2017–18.

Figure 16. Average annual number of marijuana initiates, by age group: 2015–16 to 2017–18

Source: NSDUH, 2015–16 to 2017–18

There was an annual average of 5,000 marijuana initiates between the ages of 12 and 17 during 2017–18, which is consistent with previous years. From 2016–17 to 2017–18, the average annual number of initiates 26 and older increased by 4,000. The annual number of initiates 18 to 25 years old also saw an increase from 5,000 to 7,000 during the same period.
Prescription Drugs: Misuse of Prescription Drugs Among Youth

**Indicator Description:** This indicator presents the percentage of youth who reported using prescription medications (any type) that were not prescribed to them by a doctor.

**Why Indicator is Important:** Misuse of prescription drugs may lead to consequences such as unintentional poisonings or overdose, which could lead to death, automobile crashes, addiction, and increased crime.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** There was a slight decrease in the percentage of high school students reporting that they had misused a prescription drug in the past month from 2017 (6%) to 2019 (5%).

![Figure 17. High school students reporting misuse of prescription drugs (any type) in the past month: 2011–2019](image)

*Source: MIYHS, 2011 to 2019*

- Since 2011, the proportion of students who reported misusing prescription drugs (of any type) has slightly decreased from seven percent to five percent.
- Although not shown, in 2019, high school students who perceived no risk or slight risk of harm from taking prescription drugs that were not prescribed to them were more than four times as likely to take them in the past month as high school students who did perceive a risk of harm.
Prescription Drugs: *Misuse of Prescription Drugs Among Adults*

**Indicator Description:** This measure reflects the percentage of adults in Maine who reported using prescription drugs (any type) not prescribed to them by a doctor or using them in a way other than the way in which they were prescribed, at least once in their lifetime.

**Why Indicator is Important:** Misuse of prescription drugs may lead to consequences such as unintentional poisonings, overdose, which may lead to death, dependence and increased crime.

**Data Source(s):** BRFSS, 2013–15 to 2015–2017

**Summary:** During 2015–17 the highest rates of lifetime prescription drug misuse were observed among adults between the ages of 26 and 35; about one in 10 (10%) reported misusing prescription drugs within their lifetime. Lifetime prescription drug misuse among 18 to 25-year-olds has decreased over the past several years.

![Figure 18. Misuse of prescription drugs (any type) among adults in their lifetime, by age group: 2013–15 to 2015–17*](image-url)

*Source: BRFSS, 2013–15 to 2015–17*

*2017 BRFSS estimates are preliminary; 2018 estimates are expected to be released the Fall of 2020.

- During the 2015–17 period, about four percent of adults 18 and older in Maine reported having misused prescription drugs during their lifetime. Rates of lifetime prescription drug misuse among Mainers aged 26 to 35 have observed a steady increase since 2013–15, while rates in 18 to 25-year-olds have decreased in the same period. The rates for other age groups remained relatively stable in their reported misuse.
**Prescription Drugs: Nonmedical Use of Pain Relievers Among Youth**

**Indicator Description:** This indicator presents the percentage of youth who reported using prescription pain medicines that were not prescribed to them by a doctor. This indicator was introduced in MIYHS in 2017.

**Why Indicator is Important:** Misuse of prescription pain medicines may lead to consequences such as unintentional poisonings or overdose, which could lead to death, automobile crashes, addiction, and increased crime.

**Data Source(s):** MIYHS, 2017–2019

**Summary:** About 12 percent of high school students in 2019 reported they misused a prescription pain medication during their lifetime. This is an increase of two percentage points from 2017.

*Figure 19. High school students reporting misuse of prescription pain medicine in their lifetime: 2017–2019*

*Source: MIYHS 2017 to 2019*
**Prescription Drugs: Nonmedical Use of Pain Relievers Among Adults**

**Indicator Description:** This indicator reflects the percentage of adults who reported using prescription pain relievers, specifically for reasons other than their intended purpose in the past year. In 2015–16, the pain reliever misuse indicator was redesigned to incorporate use in any way not directed by a doctor, including use without a prescription of one’s own; use in greater amounts, more often, or longer than told; or use in any other way not directed by a doctor. Prescription psychotherapeutic subtypes were revised in 2016; one effect was the comparability of codeine products between 2015 and 2016. Therefore, the data before 2015–16 could not be trended with the data collected using the new indicator.

**Why Indicator is Important:** Misuse of prescription drugs may lead to consequences such as unintentional poisonings or overdose, which could lead to death, dependence and increased crime.

**Data Source(s):** NSDUH, 2015–16 through 2017–18

**Summary:** Rates of non-medical use of prescription pain relievers continue to be higher among young adults between the ages of 18 and 25 compared to adults age 26 and older. In 2017–18, seven percent of 18 to 25-year-olds reported having misused pain relievers in the past year, which is consistent with previous years. Mainers 26 and older saw a decrease of one percentage point in non-medical use of pain relievers from 2016–17 to 2017–18.

**Figure 20. Non-medical use of pain relievers among adults in the past year, by age group: 2015–16 and 2017–18**

- From 2015-16 to 2017-18, there were no significant changes in non-medical use of pain relievers in adults 18 to 25 years old.
Other Illegal Drugs: Illicit Drug Use (Other Than Marijuana)

**Indicator Description:** This indicator reflects the percentage of individuals who used illicit drugs (other than marijuana) within the past month. Illicit drugs other than marijuana include cocaine (including crack), heroin, hallucinogens, inhalants, methamphetamine, or prescription-type psychotherapeutics used non-medically.

**Why Indicator is Important:** Use of illicit drugs can cause impaired brain function and damage to the nervous system and other organs. Even occasional use may cause heart attack, suffocation, or death.

**Data Source(s):** NSDUH, 2017–18

**Summary:** In 2017–18, the age group with the highest reported rate of illicit drug use was 18 to 25-year-olds (7%), followed by those 26 and older (3%), and youth 12 to 17 years old (2%). Rates among Mainers 26 and older have increased about one percentage point since 2016–17.

*Although not shown, rates among 18 to 25-year-olds have stayed consistent since 2013–14. From 2016–17 to 2017–18, rates among youth and adults 26 and older have increased slightly.*
Other Illegal Drugs: Cocaine Use Among Adults

Indicator Description: This indicator illustrates the percentage of Maine residents who have used cocaine. The measure reflects rates of use within the past year.

Why Indicator is Important: Cocaine is highly addictive. Use of cocaine is associated with adverse health effects such as cardiac events, seizures, and stroke. It also increases the risk of cognitive impairment, injury, and crime. Deaths involving cocaine have been rising in the state of Maine since 2014 as it is commonly mixed with other drugs such as fentanyl and heroin.\(^\text{13}\)

Data Source(s): NSDUH, 2013–14 to 2017–18;

Summary: In 2017–18, nearly eight percent of 18 to 25-year-olds and nearly two percent of Mainers 26 and older reported they had used cocaine at least once in the past year. Adults 18 to 25 saw an increase in reported use from 2016–17 to 2017–18.

Figure 22. Adults reporting cocaine use in past year, by age group: 2013–14 to 2017–18

Source: NSDUH, 2013–14 to 2017–18

- Rates among Mainers aged 18–25 have increased nearly three percentage points from 2013–14 (4.8%) to 2017–18 (7.5%), while rates among those 26 years and older have increased less than one percentage point over the same period.

**Other Illegal Drugs: Inhalant, Cocaine, Heroin, and Methamphetamine Use Among Youth**

**Indicator Description:** This indicator depicts the percentage of high school students who reported having used inhalants, cocaine/crack, heroin, or methamphetamine in their lifetime. Inhalants include substances such as glue, aerosol spray cans, paints or sprays.

**Why Indicator is Important:** Use of drugs such as inhalants, cocaine/crack, and heroin can cause impaired brain function and damage to the nervous system and other organs. Even occasional use may cause heart attack, suffocation, or death.

**Data Source(s):** MIYHS, 2013–2019

**Summary:** In 2019, seven percent of high school students reported ever using inhalants, four percent reported ever using cocaine, three percent reported ever using heroin, and three percent reported ever using methamphetamine. Although lifetime use for all four drugs has decreased from 2013 to 2019, rates have remained relatively stable in recent years.

*Source: MIYHS, 2013 to 2019*

- From 2013 to 2019, the reported lifetime rate of inhalant use declined by two percentage points, lifetime cocaine/crack use decreased by two percentage points, lifetime heroin use decreased by one percentage point, and lifetime methamphetamine use decreased by one percentage point over the same period. There have been no increases in the use of these substances from 2013 through 2019.
Other Illegal Drugs: Heroin Use Among Youth and Adults

Indicator Description: This indicator depicts the percentage and approximate number of Mainers who reported heroin use in the past 12 months.

Why Indicator is Important: Use of drugs such as heroin can cause impaired brain function and damage to the nervous system and other organs. Even occasional use may cause heart attack, suffocation, or death. Long term effects from heroin use can include but are not limited to irreversible damage to the liver or kidneys and risk of contracting communicable diseases.

Data Source(s): NSDUH, 2016–17 and 2017–18

Summary: Self-reported heroin use slightly increased in those 12 to 17 years of age (0.05% to 0.08%) and adults 26 and older (0.45% to 0.65%) from 2016-17 to 2017-18. Reported rates of use in young adults 18 to 25 (1.24% to 1.10%) slightly decreased over the same period. However, this is still the group with the highest reported rate of heroin use.

Source: NSDUH, 2016–17 to 2017–18

- In 2017–18, 0.65 percent of Mainers aged 12 and older (approximately 8,000 residents) self-reported that they had used heroin within the past year. This is up from 0.51 percent (about 6,000 residents in 2016–17). The highest prevalence was observed among 18 to 25-year-olds, reporting a rate of 1.10 percent.
Substance Use and Pregnancy: Substance Use During and Prior to Pregnancy

Indicator Description: This indicator reflects the percentage of mothers who reported using substances before or while they were pregnant.

Why Indicator is Important: Exposure to alcohol can cause damage to the fetus during all stages of pregnancy. Because the minimum quantity of alcohol required to produce those damaging effects is unknown, the American Academy of Pediatrics recommends complete abstinence from alcohol for pregnant women. Babies born to mothers who smoked during pregnancy can have lower birth weights than those whose mothers did not smoke. The U.S. Surgeon General warns against smoking during pregnancy. Substance use during pregnancy can cause a host of short-term and long-term developmental delays to the fetus and child.

Data Source(s): PRAMS, 2014–2018

Summary: In 2018, more than one in 10 (12%) of women reported using cigarettes or marijuana while pregnant, while nine percent of women reported using alcohol during their last trimester of pregnancy. The rate of cigarette use among pregnant women has been decreasing in recent years, while we observe an uptick in marijuana use. Prescription pain reliever use (for any reason) one month prior to being pregnant has been around four percent since 2016. E-cigarette use during the last trimester has also been steady at around one percent. Younger mothers and mothers with less education were more likely to report cigarette use during their third trimester. Nearly one-third of women who had less than a high school diploma reported using cigarettes during their last trimester.

In 2018, 12 percent of women who recently had given birth reported either smoking at least one cigarette during their last trimester or using marijuana at least once during any time throughout their pregnancy. Cigarette use rates among this population have declined in recent years, while marijuana usage has increased. After observing a steady increase from 2015 (6%) to 2017 (10%), the rate of alcohol use during the last trimester decreased slightly to nine percent. Prescription pain reliever use (for any reason) one month prior to pregnancy has been stable around three and four percent. E-cigarette use during last trimester has also remained steady between one and two percent.

*Source: PRAMS, 2017 and 2018*

*Due to small sample sizes, reliable estimates are not available for the age group 19 and under*

Regarding level of education achieved, in both 2017 and 2018, cigarette use rates during the last trimester were highest among those with less than a high school diploma, followed by those with only a high school diploma. As for age, rates of cigarette use were highest among women 19 and under (29%), followed by 20 to 24-year-olds (19.2%), 25 to 34-year-olds (9.8%), and women 35 and older (3.4%). Note: Sample size was too small to produce a reliable estimate for cigarette use among those 19 and under in 2018.
Consequences Resulting from Substance Use and Misuse

Both individuals and communities suffer the consequences of substance use in terms of increased health care need, criminal justice involvement, resources, and costs. While a great deal of information regarding substance use can be obtained from the data described in the previous section (consumption), information on the effects of that use on individuals and communities can be derived from what has come to be called “consequence” data. Consequences are defined as the social, economic, and health problems associated with the use of substances such as alcohol, tobacco, marijuana, prescription and illicit drugs. Examples of these include illnesses related to alcohol and other drug use, drug overdose deaths, property and personal crimes, driving accidents, poisonings, and suicides. Given the likely impact of COVID-19 on substance use, the SEOW will continue to track the consequences that come with potential increased substance use.

Risky alcohol use continues to have detrimental effects on the health and safety of Mainers, particularly among youth and young adults. Impaired (alcohol/drug-related) crash fatalities are a major consequence of alcohol consumption. More than one in four fatal motor vehicle crashes in 2019 involved alcohol/drugs. From 2015 to 2019, the number of overall motor vehicle crashes increased by ten percent, while the number of crashes involving impaired drivers increased by seven percent. Arrests related to operating under the influence have remained stable. It should be noted that Mainers ages 30 to 39 observed a substantial increase in OUI arrests from 2014 to 2018. For the first time in many years, liquor law violations among youth in Maine increased slightly from 2017 to 2018.

For the past several years, consequences arising from synthetic opiates (e.g., prescription pain relievers) have declined as those related to illicit opioids (e.g., heroin, non-pharmaceutical fentanyl) have become more prominent. This overall shift to more potent and volatile opioids has had a profound impact on overdoses, crime, and health in Maine. After observing some relief in terms of morbidity and mortality from illicit drugs in 2018, there has been another small spike in associated outcomes.

In 2019, there was considerable increase in fatal overdoses involving non-pharmaceutical fentanyl (illicitly manufactured) reported from 2018. Non-pharmaceutical fentanyl continues to play a major role in drug-related deaths, comprising more than two-thirds of total deaths, whereas the influence of heroin began to decline in 2016. Benzodiazepines and methadone-attributed deaths remained steady from 2018 to 2019. Just over one in four overdose deaths involve alcohol, while nearly one in three overdose deaths involved cocaine. The proportion of overdoses involving cocaine has increased significantly in the past few years as it is commonly being mixed with other deadly drugs. Most overdose deaths continue to occur among Mainers between 26 and 49.

As Maine and the Northeast grapple with the opioid epidemic, it is crucial to monitor other emerging drugs as well. Drugs such as methamphetamine, cocaine, and other potentially addictive and dangerous prescription drugs (e.g., benzodiazepines, stimulants) have had a progressively graver impact in Maine as well. Trafficking investigations conducted by the Maine
Drug Enforcement Agency (MDEA) related to heroin have decreased by more than two-thirds since 2016. Additionally, the number of MDEA manufacture investigations as well as the number of lab incidents linked to methamphetamines has decreased drastically over the past few years. The number of methamphetamine sale investigations, however, has increased by nearly 150 percent from 2017 to 2019. This is due to more methamphetamine being trafficked into the state, whereas less methamphetamine is being made in the state of Maine, which has led to fewer manufacturing arrests and lab incidents than in previous years. MDEA investigations related to the trafficking of cocaine increased substantially from 2016 to 2018 but decreased from 2018 to 2019.

As for drug possession arrests, those related to other drugs and dangerous non-narcotics increased by about one-fifth from 2014 to 2018, while arrests for the possession of marijuana saw a sizeable decrease over the same period. In 2018, one-third of drug offense arrests for possession were for other dangerous non-narcotics. The shifting landscape of Maine’s laws and regulations regarding the medicinal and adult use of marijuana continues to have a significant impact on drug possession arrests in Maine as marijuana arrests account for fewer than three in 10 possession arrests. In 2018, for the first time, marijuana was eclipsed for the highest proportion of possession arrests by other dangerous non-narcotics, like benzodiazepines, steroids, stimulants, synthetic cannabis, bath salts, methamphetamine, hallucinogens, and barbiturates.

EMS responses related to alcohol have been increasing for the past several years. From 2015 to 2019, alcohol overdoses increased substantially. Rates of alcohol overdose responses were disproportionately highest among adults aged 18 to 25 years old. However, the age group with the most alcohol-related EMS responses was those 55 and older. This is the first time in recent history that this age group has surpassed the number of EMS responses to those aged 36 to 54. Although, alcohol overdose responses among adults 36 and older continue to steadily increase from year to year. In 2019, the rates of opioid and non-opioid overdose EMS responses were highest among 26 to 35-year-olds. After greatly increasing from 2015 to 2017, the number of naloxone incidents continues to decrease. In 2019, nearly seven out of 10 individuals receiving naloxone by EMS were male. Rates continue to be disproportionately higher among males 26 to 54 years old.

According to the most recent data available from the Maine Syndromic Surveillance System, alcohol is the most common substance for ED visits related to substance use. Males are more likely than females to be admitted to the ED for substance use regardless of the substance. The greatest number of alcohol incidents in the ED is seen in older adults aged 50 to 63. The greatest number of marijuana and opioid visits are observed in young and middle-aged adults (those 20 to 49 years of age). That being said, there has been a decrease in overall ED visits related to marijuana and opioids from 2018 to 2019.

Substance use during pregnancy can cause a myriad of short- and long-term developmental deficits to the fetus and child. In 2019, 858 live births in Maine reported the infant had been exposed and/or affected by substances; this accounted for just over seven percent of the live
births in Maine. After increasing from 2015 to 2016, the number of substance-exposed infant notifications declined from 2016 to 2019. While progress has been made, which is seen in the number of substance-exposed infants declining, there is still room for improvement. Perhaps additional or more intensive programs for expecting mothers are needed to combat the issue of substance-exposed infants.
Criminal Justice Involvement: *Arrests Related to Alcohol*

**Indicator Description:** This indicator reflects arrests related to alcohol and includes operating under the influence (OUI) and liquor law violations. The data includes those who were released without having been formally charged.

**Why Indicator is Important:** OUI and liquor law arrest rates can be an indication of the rate of criminal behavior, but it is important to note that they are also an indication of the level of law enforcement deployed. Arrest rates are expected to increase with increased enforcement regardless of whether criminal behavior changes.

**Data Source(s):** DPS-UCR, 2014–2018

**Summary:** The number of OUI arrests have remained stable over the past several years, whereas arrests pertaining to violating liquor laws (excluding OUIs) have decreased substantially. Liquor law violations among those under 21 have decreased considerably from 2014 to 2018. OUI violations among drivers 18 and under have decreased by nearly half from 2017 to 2018. While adults aged 21 to 29 continue to receive the highest number of OUI arrests, Mainers ages 30 to 39 observed a considerable increase (26%) in OUI arrests from 2014 to 2018.

![Figure 27. Adult arrests (18+ years old) related to alcohol, by arrest type: 2014–2018](source: DPS-UCR, 2014 to 2018)
• In 2018, there were 5,784 adult arrests for OUIs compared to 1,658 arrests for breaking liquor laws. The number of adult OUI arrests has remained relatively stable since 2015, while the number of adult liquor violations decreased by 23 percent from 2015 to 2018.

Figure 28. Juvenile arrests (<18 years old) related to alcohol, by arrest type: 2014–2018

![Graph showing juvenile arrests related to alcohol by arrest type from 2014 to 2018.](image)

Source: DPS-UCR, 2014 to 2018

• Alcohol-related arrests among juveniles differ from those of adults in that the majority of arrests are related to liquor law violations. In 2018, there were 389 juvenile arrests for breaking liquor laws and 27 for OUI arrests. Juvenile liquor law violations have increased by five percent from 2017 to 2018, whereas juvenile OUI arrests decreased by 53 percent in the same time period.

Figure 29. Arrests related to alcohol, by age group: 2018

![Bar chart showing arrests related to alcohol by age group in 2018.](image)

Source: DPS-UCR, 2018
In 2019, as can be seen in previous years, juveniles are more likely to be arrested for liquor law violations while adults are more likely to be arrested for OUI.

As previously noted, the number of arrests related to OUI and liquor law violations differs among adults and juveniles. This pattern remains when comparing the number of arrests among those of legal drinking age to those who are under 21. In 2018, there were 389 liquor law violations for people under 18 and 1,033 for people between the ages of 18 to 20. In comparison, there were 193 liquor law violations for those between the ages of 21 and 29, and even fewer among older age groups.

**Figure 30. Arrests related to liquor law violations, by age group: 2014 to 2018**

*Source: DPS-UCR, 2014 to 2018*
The opposite can be seen in OUI violations. In 2018, there were 27 arrests for those under the age of 18 and 272 for 18 to 20-year-olds, compared to 1,756 OUIs for those between the ages of 21 and 29 (more than any other age group). While the number of OUI violations for most age groups appear to be stable, Mainers ages 30 to 39 observed a 26 percent increase in OUI arrests from 2014 to 2018. It is worth noting that the number of OUIs generally decreases with age.

Source: DPS-UCR, 2014 to 2018
Criminal Justice Involvement: Arrests Related to Drugs

Indicator Description: This indicator reflects the number of arrests made by Maine law enforcement agencies that were related to drugs and includes possession only. Categories for drug arrests are rather broad. “Opium, cocaine, and derivatives” arrests mostly encompass heroin/morphine and cocaine/crack. “Synthetic narcotic” arrests refer mostly to prescription drug opiates. “Other dangerous non-narcotics” include but are not limited to benzodiazepines, steroids, stimulants, synthetic cannabis, bath salts, methamphetamine, hallucinogens, and barbiturates.

Why Indicator is Important: Arrest rates for drug possession can be an indication of the rate of criminal behavior, but it is important to note that they are also an indication of the active level of law enforcement. Arrest rates are expected to increase with increased enforcement regardless of whether criminal behavior changes.

Data Source(s): DPS-UCR, 2015–2018

Summary: After observing a dramatic drop from 2016 to 2017, arrests related to the possession of drugs increased by six percent from 2017 to 2018. In 2018, one in three drug offense arrests for possession were for other dangerous non-narcotics. The number of arrests due to marijuana possession has continued to decrease. From 2017 to 2018, there was a substantial increase (40%) in synthetic narcotic possession arrests and an eight percent increase in other dangerous non-narcotic arrests.

Source: DPS-UCR, 2014 to 2018
The total number of arrests for drug possession increased by six percent from 2017 (2,382) to 2018 (2,518). Juvenile drug possession arrests decreased by 38 percent from 2014 (409) to 2018 (251). After observing a dramatic drop from 2016 to 2017, drug possession arrests for adults increased by nine percent from 2017 (2,081) to 2018 (2,266).

![Figure 33. Law enforcement drug arrests for possession by type: 2018](image)

Source: DPS-UCR, 2018

Other dangerous non-narcotics comprised the largest portion of drug arrests for possession in 2018 at 32 percent, followed closely by marijuana at 29 percent, opium, cocaine, and derivatives at 25 percent, and synthetic narcotics at 14 percent. This is the first year in recent history that marijuana was not the substance with the highest proportion of possession arrests.

</tbody>
</table>

*Source: DPS-UCR, 2014 to 2018*

- From 2017 to 2018, there was a 40 percent increase in synthetic narcotics and an eight percent increase in other dangerous non-narcotic arrests. Over the same period, there was a decrease of three percent in opium, cocaine, and derivatives arrests and a six percent decrease in marijuana arrests. It is worth noting that arrests related to the possession of marijuana decreased by 74 percent from 2014 to 2018.
Criminal Justice Involvement: Drug Enforcement Agency Drug Trafficking and Manufacturing Investigations

**Indicator Description:** This indicator reflects trafficking investigations made by Maine’s Drug Enforcement Agency, by drug type. The MDEA through its regional multi-jurisdictional task forces is the lead state agency in confronting drug trafficking crime.

**Why Indicator is Important:** Drug investigation counts can be an indication of the rate of criminal behavior, but it is important to note that they are also an indication of the active level of law enforcement. Drug manufacturing investigations are expected to increase with increased enforcement regardless of whether criminal behavior changes.

**Data Source(s):** MDEA-UCR, 2015–2019

**Summary:** In 2019, the most common substance involved in drug trafficking investigations was cocaine, which was involved in 260 investigations. There were 157 investigations around heroin and 121 for other opiates. For the second year in a row, cocaine was the primary drug in trafficking investigations. Heroin investigations have been decreasing since 2016. Cocaine investigations decreased from 2018 (297) to 2019 (260). There was a decrease of 39 percent in methamphetamine manufacturing investigations from 2018 (53) to 2019 (38), however there was a 63 percent increase in investigations related the sale of methamphetamine during this time frame.

![Figure 35. MDEA drug trafficking investigations, by drug type: 2015–2019](source:MDEA, 2015 to 2019)
There was a decrease of 39 percent in methamphetamine manufacturing investigations from 2018 to 2019.

From 2018 to 2019, there was a 63 percent increase in methamphetamine sale investigations.

Although not explicitly shown, there were 35 methamphetamine lab/dumpsite-related responses by the MDEA in 2019, which is decreased from 51 such responses in 2018.

Source: MDEA, 2017 to 2019
Criminal Justice Involvement: *Pharmacy Robberies*

**Indicator Description:** This indicator reflects the number of pharmacy robberies in the state of Maine as tracked by the Maine Drug Enforcement Agency.

**Why Indicator is Important:** The number of pharmacy robberies can indicate the demand for pharmaceutical drugs. Pharmacy robberies contribute to a higher demand for law enforcement resources, lost earnings for retailers, and trauma to those involved. In addition, robberies increase the availability of prescription drugs in the community, which contribute to misuse by individuals without a prescription.

**Data Source(s):** MDEA-UCR, 2015–2019

**Summary:** Pharmacy robberies have decreased from 2015 (8 robberies) and have stayed steady at two robberies per year since 2017.

![Graph showing the number of pharmacy robberies in Maine from 2015 to 2019](image)

Source: MDEA, 2015 to 2019

- In 2019, two pharmacies were robbed. This is consistent with 2017 and 2018 and represents a 75 percent decrease from 2015.
**Motor Vehicle Crashes Involving Alcohol/Drugs: Impaired Driving**

**Indicator Description:** This indicator shows the number of motor vehicle crashes in which alcohol was a factor, meaning at least one driver had consumed medication, drugs, or alcohol.

**Why Indicator is Important:** Motor vehicle crashes are the leading cause of death in the first three decades of Americans’ lives.\(^\text{14}\) Nationally, impaired driving crashes account for 28 percent of all traffic-attributed deaths.\(^\text{15}\) Drugs other than alcohol (legal and illegal) are involved in about 16 percent of motor vehicle crashes. In 2018, 12 million Americans aged 16 and older reported driving under the influence of marijuana and 2.3 million reported driving under the influence of illicit drugs other than marijuana during the previous 12 months.\(^\text{16}\)

**Data Source(s):** MDOT, BHS, 2015–2019

**Summary:** The annual number of motor vehicle crashes has increased by seven percent from 2015 to 2019. However, the proportion of alcohol- and/or drug-related motor vehicle crashes has remained stable at roughly four percent.

**Figure 38. Number of motor vehicle crashes, by whether they involved impaired drivers: 2015–2019**

---

The total number of motor vehicle crashes has increased by seven percent from 2015 (32,928) to 2019 (35,242). The number of crashes involving impaired drivers also increased seven percent from 2015 (1,197) to 2019 (1,276). However, it should be noted that the proportion of crashes related to alcohol and/or drugs has remained stable at around four percent.
Motor Vehicle Crashes Involving Alcohol/Drugs: Alcohol/Drug-Related Motor Vehicle Crash Rate

Indicator Description: This indicator presents the number of motor vehicle crashes involving impaired drivers under the influence of alcohol and/or drugs/medication, relative to the licensed population. The rate per 100,000 allows the frequency with which an occurrence emerges within a population over time to be visualized. In this case, the population is the number of licensees (among a particular age group) in Maine.

Why Indicator is Important: One in four of all motor vehicle crashes resulting in fatalities involved alcohol and/or drugs, regardless of age.

Data Source(s): MDOT, BHS, 2015–2019

Summary: The age group with the most alcohol or drug related crashes continues to be those aged 21–24, with 359.8 crashes related to alcohol and drugs occurring in every 100,000 licensees. In 2019, those 55 years and older have the lowest rate of alcohol- and drug-related crashes with 42.0 per every 100,000 licensees. For the second year in a row, 16 to 20-year-olds saw a relatively large (10%) decrease in alcohol- and drug-related crashes

Figure 39. Alcohol/drug-related motor vehicle crash rate per 100,000 licensees, by age group: 2015–2019

Source: MDOT, BHS, 2015 to 2019
In 2019, Maine drivers ages 21 to 24 had the highest alcohol-related crash rate (359.8 per 100,000 licensees); rates among this age group have shown a slight but steady decrease since 2016. The second-highest rates of alcohol/drug-related motor vehicle crashes in 2019 were observed among drivers between the ages of 25 to 34 (268.3 per 100,000 licensees), followed by drivers ages 35 to 44 (179.7 per 100,000 licensees).
Motor Vehicle Crashes Involving Alcohol/Drugs: Number of Fatal Motor Vehicle Crashes Involving Alcohol/Drugs

Indicator Description: This indicator presents the number of fatal motor vehicle crashes where alcohol was a factor in the crash. This means that at least one driver had a blood alcohol content (BAC) of at least .08 or greater and/or was under the influence of drugs/medication. This indicator includes total fatalities of anyone (e.g., pedestrian, passenger) involved in the crash. It is important to note that small fluctuations from year to year do not indicate an overall trend.

Why Indicator is Important: Alcohol/drug-related crash fatalities are a major consequence of alcohol/drug consumption. Research has also shown that people mix various substances including alcohol which have a number of different effects on the individual’s cognitive ability to perform operations while driving such as swerving or slowed reaction times. Driving is a responsibility and when someone consumes alcohol or drugs, it becomes exponentially more dangerous for the driver, passengers and others on the road and increases the likelihood of crashes and associated negative consequences such as death.17

Data Source(s): MDOT, BHS, 2015–2019

Summary: Of the fatal motor vehicle crashes occurring in 2019, 27 percent involved alcohol and/or drugs. There were 157 fatal motor vehicle crashes in 2019 and 43 involved an impaired driver.

Figure 40. Number of fatal motor vehicle crashes, by whether they involved impaired drivers: 2015–2019

Source: MDOT, BHS, 2015 to 2019

*2018 and 2019 results are preliminary

- The number of fatal crashes increased from 136 in 2018 to 157 in 2019, as did the percentage that involved impaired drivers (25% in 2018 to 27% in 2019).

Motor Vehicle Crashes Involving Alcohol/Drugs: Alcohol/Drug-Related Motor Vehicle Crash Fatality Rate

**Indicator Description:** This indicator presents the number of fatalities resulting from motor vehicle crash fatalities that involved alcohol (drivers with a blood alcohol content of .08 or greater) and/or drugs, relative to the licensed population. The rate per 100,000 allows us to see the frequency of this occurrence within a population over time. In this case, the population is the number of licensees in Maine. Where applicable, the number of licensees used to calculate the rate reflects the relevant age group.

**Why Indicator is Important:** More than one in four of all motor vehicle crashes resulting in fatalities involve alcohol and/or drugs. The National Traffic Highway Safety Administration reports that approximately one-third of all traffic crash fatalities in the United States involve drunk drivers. In 2018, there were 10,511 people killed in these crashes. In fact, on average over the 10-year period from 2009–2018, more than 10,000 people died every year in drunk-driving crashes.¹⁸

Data Source(s): MDOT/BHS, 2013–15 to 2017–19

**Summary:** In 2017–19, the rate of alcohol/drug-related motor vehicle crash fatalities was highest among 25 to 34-year-olds, followed by 21 to 24-year-olds. This is the first period that 21 to 24-year-olds do not have the highest rate of alcohol/drug-related motor vehicle crash fatalities. Rates increased for all age groups with the exception of 21 to 24-year-olds and 45 to 54-year-olds, who both saw a decrease.

For the first time in recent history, more impaired drivers age 25 through 34 had the highest rate of impaired driving fatalities (7.8 per 100,000), surpassing 21 to 24-year olds (7.6 per 100,000).

Impaired driver fatality rates start to decrease at the age of 35, which is consistent with previous years.

Overdoses and Related Deaths: EMS Overdoses

Indicator Description: This indicator shows the number of persons receiving help from Emergency Medical Services (EMS) related to an overdose from 2015 to 2019. These data are based on the primary impression (involving an intoxicant) given by the emergency responder at the scene. Alcohol data is trended over the years. Opioid and other drug overdose data is tracked differently starting in 2019, thus cannot be trended with previous years. Opioid overdoses include those that presented with and without a coma. Opioid overdoses can involve either pharmaceutical (e.g., Oxycodone) or illicit (e.g., heroin) opioids.

Why Indicator is Important: Overdosing on a substance can cause serious physical harm resulting in hospitalization and even death. Responding to overdoses also uses valuable EMS resources. Overdose prevention data from EMS records have been used for surveillance of opioid overdoses on a local level. Monitoring nonfatal overdose events using EMS records provides a more complete evaluation of the potential injury burden and a means of benchmarking for communities and EMS agencies to better address the evolving opioid epidemic.\(^\text{19}\)

Data Source(s): Emergency Medical Services, 2015–2019

Summary: The number of alcohol overdoses increased by 16 percent from 2018 (3,270) to 2019 (3,809). In 2019, half of EMS overdose responses were for alcohol, about a third were related to drug excluding opioids or cannabis, nearly one in five were for opioids, and one percent were for cannabis. EMS overdose responses related to alcohol or opioids were twice as common among males. Rates of alcohol overdose responses were slightly higher among Mainers aged 18 to 25 but did not vary much among other adult age groups, while non-opioid and opioid responses were substantially higher among Mainers aged 26 to 35. Furthermore, alcohol overdose responses among adults 36 and older have been steadily increasing for the past several years.

In 2019, based on the primary impression of the EMS responder, there were 3,809 (50%) responses related to an overdose from alcohol, followed by 2,324 (31%) responses related to other drugs (excluding opioids and cannabis), 1,323 (18%) responses related to opioids, and 109 (1%) related to the overdose of cannabis.

Source: EMS, 2019

Figure 43. Number of overdose EMS responses, by drug type and gender: 2019

Source: EMS, 2019
• In 2019, there were twice as many alcohol overdose EMS responses among males (2,549) as compared to females (1,229). Although not explicitly shown, males accounted for two-thirds (67%) of the alcohol overdose EMS responses.

• Similar to alcohol, EMS overdose responses related to opioids were more than twice as common among males (906) as compared to females (407). Although not depicted, 69 percent of EMS opioid overdose responses involved males.

• There was not much variation regarding gender with EMS overdose responses related to other drugs (excluding opioids and cannabis) or those responses involving only cannabis.

Source: EMS, 2019

• In 2019, EMS overdose responses related to alcohol were most common among those 55 and older (1,378), followed by Mainers 36 to 54 (1,309), 26 to 35 (528), 18 to 25 (511), and those under 18 (83).

• EMS responses related to other drugs (excluding opioids and marijuana) were most common among Mainers 36 to 54 (734), followed by 25 to 35-year-olds (612), the 55 and older population (421), 18 to 25-years-olds (270), and minors under 18 (220).

• EMS overdose responses related to cannabis were most common among adults between the ages of 36 to 54 (34), followed by Mainers 55 and older (29), 18 to 25-year-olds (19), 26 to 35-year-olds (16), and minor under 18 years of age (11).
The EMS alcohol-related overdose response rate was highest among adults 18 to 25 in 2019 (40.8 per 100,000), however there wasn’t a lot of variation among adult age groups.

The highest rate of EMS responses related to an overdose of other drugs (excluding opioids and cannabis) was observed among 26 to 35-year-olds with 42.9 responses per 10,000 residents; this rate was followed by 18 to 25-year-olds (25.8 per 10,000), and 36 to 54-year-olds (21.7 per 10,000).

In 2019, the rate of EMS responses related to opioid drug overdoses was highest among Mainers 26 to 35 with 37.7 responses per 10,000 residents; this rate was more than twice the rate of the next highest rate among 36 to 54-year-olds (14.6 per 10,000).

When compared to other overdose EMS responses, rates involving cannabis are much smaller. The highest rate of EMS cannabis overdose responses was observed among Mainers 26 to 35, with 1.1 responses per 10,000 residents. Similar to alcohol, there was not much variance among adult age groups.

Source: EMS, 2019
An increase of 768 (16%) overdose EMS responses for alcohol were recorded from 2018 (3,270) to 2019 (3,809). Since 2015, there has been a 77 percent increase in EMS responses for alcohol.

Source: EMS, 2015 to 2019
There was an increase in alcohol-related EMS responses for all age groups from 2018 to 2019.

In 2019, the age group with the most alcohol-related EMS responses was those 55 and older. This group saw an increase of 35 percent from 2018 to 2019. This is the first time in recent history that this age group has surpassed the number of EMS responses to 36 to 54-year-olds.

**Source: EMS, 2015 to 2019**
**Overdoses and Related Deaths: Syndromic Surveillance Overdoses**

**Indicator Description:** Maine’s hospital syndromic surveillance system collects information from hospital emergency departments and, in some cases, their affiliated urgent care centers. Maine CDC has 33 hospital emergency departments that participate in the syndromic system. This indicator shows the number of persons admitted to the emergency department due to an overdose from 2018 to 2019.

**Why Indicator is Important:** Overdosing on a substance can cause serious physical harm resulting in hospitalization and even death. Additionally, overdoses utilize valuable emergency department resources. Syndromic surveillance systems are used to rapidly identify outbreaks and provide situational awareness of changes in drug overdose-related emergency department (ED) visits at the local, state, and regional level. These systems gather aggregate data on ED visits involving suspected all drug, all opioid, heroin, and all stimulant overdoses. This data includes demographic characteristics of those who overdosed, such as sex, age, and county of patient residence. Jurisdictions share their data with the CDC as frequently as every two weeks, either by uploading data using a secure server or allowing staff access to their data in CDC’s National Syndromic Surveillance Program’s (NSSP) BioSense platform.²⁰

**Data Source(s):** CDC Syndromic Surveillance System, 2018 and 2019

**Summary:** In 2019, there were nearly 19,000 alcohol-related ED visits, followed by marijuana related visits (4,583), and opioid (pharmaceutical and illicit) overdose visits (1,214). Since 2018, alcohol ED overdose visits have increased slightly (2%), while those related to marijuana and opioids have decreased by 11 and 12 percent, respectively. Overall, males are more likely to be admitted to the ED as a result of an overdose regardless of substance. Alcohol related ED visits are most prevalent among Mainers between the ages of 35 and 64, whereas ED visits related to either marijuana or opioids are more common among people between the ages of 20 and 49.

---

Figure 48. Number of ED visits related to substance use, by substance: 2018 and 2019

Source: Syndromic Surveillance System, 2018 to 2019

- The number of alcohol-related emergency department (ED) visits increased by two percent, from 18,241 in 2018 to 18,621 in 2019. During the same time frame, the number of marijuana-related ED visits decreased by 11 percent (from 5,140 to 4,583) while those related to opioids decreased by 12 percent (from 1,372 to 1,214).

Figure 49. Number of ED visits related to substance use, by age and substance type: 2019

Source: CDC Syndromic Surveillance System, 2019
In 2019, most alcohol-related emergency department visits were among those 50 to 64 years of age (6,475), while most marijuana or opioid related visits were seen in adults 20 to 34 years old (1,832 and 529 respectively).

*Source: CDC Syndromic Surveillance System, 2019*

In 2019, Mainers between the ages of 35 and 49 had the highest rate of alcohol-related emergency department visits with 224.3 visits per 10,000 residents; followed closely by 50 to 64-year-olds (209.1 per 10,000). Marijuana-related ED visits were disproportionately higher among younger adults ages 20 to 24 (78 per 10,000). The highest rates of overdose ED visits related to opioids were observed among Mainers aged 20 to 34 (22.5 per 10,000) and those 35 to 49 (16.9 per 10,000).
Males had a greater likelihood of being admitted to the emergency department than females for all three substances in 2019. Compared to females, males were more than twice as likely to be admitted to the emergency department for alcohol, 1.4 times as likely to be admitted for a marijuana, and 1.7 times as likely to be admitted for an opioid overdose.

Overdoses and Related Deaths: Naloxone Administrations

Indicator Description: This indicator shows the number of naloxone administrations and the number of individuals receiving doses from Emergency Medical Services related to an opioid overdose. Naloxone is a medication administered to patients who have experienced an overdose related to an opioid (e.g., prescription painkillers, heroin, or morphine). Some individuals may have received multiple administrations/doses of naloxone.

Why Indicator is Important: Overdosing on a substance can cause serious physical harm resulting in hospitalization and even death. Responding to overdoses also uses valuable EMS resources. This indicator also provides a sense of the prevalence of all opioid overdoses, including those that did not result in death.

Data Source(s): Emergency Medical Services, 2015–2019

Summary: The number of incidents where EMS administered naloxone peaked in 2017 and has been declining since with 1,287 in 2019. In 2019, nearly seven out of 10 individuals receiving naloxone by the EMS were male. Rates continue to be disproportionately highest among males 26 to 34 years old.

Figure 52. Number of EMS responses with naloxone* incidents: 2015–2019**

Source: EMS, 2015 to 2019

*Naloxone, also known as Narcan, is a medication administered to counter the effects of an overdose due to opioids.

**2019 data are preliminary

- In 2019, 1,287 individuals were administered naloxone by emergency medical responders. This is a decrease of nine percent since from 2018 (1,419).
Figure 53. EMS naloxone* administration incidents, by gender and age: 2019**

*Naloxone is a medication administered to counter the effects of an overdose due to opioids.
**2019 data are preliminary

- In 2019, out of 1,287 incidents (with known ages) receiving naloxone administrations from EMS responders, 67 percent were male, and 33 percent were female. The group with the greatest number of EMS naloxone administration incidents in 2019 was 36 to 54-year-old males (353). Females most likely to receive a naloxone administration were also in this age group (154). This is consistent with previous years.

*Naloxone, also known as Narcan, is a medication administered to counter the effects of an overdose due to opioids.

**2019 data are preliminary

- In 2019, the highest rate of individuals receiving naloxone administrations from EMS responders was for males 26 to 35 (371.8 per 100,000). This age group experienced the highest rate regardless of gender as well (276.1 per 100,000). The group with the second-highest rate of naloxone administrations from EMS providers were males ages 36 to 54 (213.2 per 100,000).
Overdoses and Related Deaths: Deaths Due to Overdose

Indicator Description: This measure reflects the number of deaths where the cause of death was directly related to the consumption of one or more substances. This excludes deaths where a substance may have been ingested prior to engaging in a behavior that resulted in death (e.g., drunk driving) or where lifetime substance use may have impacted health (e.g., alcoholic cirrhosis). Pharmaceutical opioids are drugs used in medical treatment; illicit drugs are those illegally produced and sold outside of medical channels. This analysis includes Maine decedents as well as non-residents that died from an overdose while in Maine.

Why Indicator is Important: The most extreme consequences of alcohol and drug use is overdose death, where the substance(s) plays a direct role in an individual’s death. These are potentially preventable deaths. In 2018, 67,367 drug overdose deaths occurred in the United States. The age-adjusted rate of overdose deaths decreased by 4.6 percent from 2017 (21.7 per 100,000) to 2018 (20.7 per 100,000). Opioids—mainly synthetic opioids (other than methadone)—are currently the main contributor in drug overdose deaths. Opioids were involved in 46,802 overdose deaths in 2018 (69.5% of all drug overdose deaths). Two out of three (67.0%) opioid-involved overdose deaths involve synthetic opioids.21

Data Source(s): Office of Chief Medical Examiner/Dr. Marcella Sorg,22 2015–2019

Summary: In 2019, illicit drug deaths (301) continue to be more common than pharmaceutical drug deaths (246). Both drug death types saw an increase from 2018 to 2019. In total, 380 deaths occurred due to illicit and pharmaceutical drugs. It is important to note that deaths involving pharmaceuticals and illicit drugs are not mutually exclusive.

Figure 55. Number of deaths* caused by pharmaceuticals and/or illicit drugs, alone or in combination: 2015–2019

*Deaths involving pharmaceuticals and illicit drugs are not mutually exclusive.

- After decreasing for the first time since 2011 in 2018, drug deaths increased again in 2019. Illicit drug overdose deaths continue to outnumber overdoses related to pharmaceuticals (246 pharmaceutical-related deaths compared to 301 illicit drug-related deaths).

Source: Dr. Marcella Sorg/Office of the Chief Medical Examiner, 2015 to 2019
**Overdoses and Related Deaths: Overdose Deaths Associated with Specific Substances**

**Indicator Description:** When a death is investigated, the Medical Examiner determines what substances contributed to the individual’s death. This measure examines the percent of drug overdose deaths associated with certain types of substances. Note that more than one substance can be determined to have contributed to the death.

**Why Indicator is Important:** One of the most extreme consequences of alcohol and drug use is overdose death, where the substance(s) play a direct role in an individual’s death. These are potentially preventable deaths. In addition, some substances are more lethal than others. Drug overdose deaths may involve multiple drugs; therefore, a single death might be included in more than one category when describing the number of drug overdose deaths involving specific drugs. For example, a death that involved both heroin and fentanyl would be included in both the number of drug overdose deaths involving heroin and the number of drug overdose deaths involving synthetic opioids other than methadone.23

**Data Source(s):** Office of Chief Medical Examiner/Dr. Marcella Sorg,24 2015–2019

**Summary:** In 2019, non-pharmaceutical fentanyl continues to be the most common drug type involved in drug-related deaths (259). Cocaine (110) and alcohol (104) are also regularly involved in drug-related deaths. All drugs with the exception of heroin/morphine and oxycodone experienced an increase in 2019.

---

Although not shown, 84 percent of drug deaths were caused by opioids, generally in combination with other drugs or alcohol. The number of non-pharmaceutical fentanyl-related deaths is on the rise again in 2019, after decreasing from 2017 to 2018. In 2019, the rate of deaths related to cocaine has started to increase again.
Figure 57. Percent of drug deaths** involving specific drug types†:
2015–2019

Source: Dr. Marcella Sorg/OCME, 2015 to 2019

†Some deaths may be caused by more than one key drug.
**Deaths caused by known pharmaceutical morphine removed from total.
* include acetyl fentanyl but excludes pharmaceutical fentanyl (e.g., fentanyl patches).

- Non-pharmaceutical fentanyl was involved in 68 percent of drug deaths in 2019 and is the most commonly seen drug in drug deaths by far. Following nonpharmaceutical fentanyl is cocaine (29%), ethanol/alcohol (27%), pharmaceutical opioids (25%), benzodiazepines (22%), and heroin/morphine (16%).
Overdoses and Related Deaths: *Rate of Deaths Due to Substance Use*

**Indicator Description:** This measure estimates the rate of deaths due to substance use or overdose per 100,000 people. It reflects deaths physically occurring within the state of Maine, which includes non-Maine residents dying in Maine, but excludes Maine residents who died outside of Maine. The rate per 100,000 allows us to see the frequency of an occurrence within a population over time. These data encompass overall substance use and overdose deaths and allow us to see the impact on Maine as a whole in comparison to the breakdown of separate substances seen in the previous indicators.

**Why Indicator is Important:** Drug-induced deaths can be mitigated by programs to prevent substance use, accidental poisoning, suicide and fatal interaction among medications. In 2018, the age-adjusted rate of drug overdose deaths in the United States was 4.6 percent lower than the rate in 2017. The age-adjusted rate of drug overdose deaths increased from 6.1 per 100,000 standard population in 1999 to 21.7 in 2017. The rate increased on average by 10 percent per year from 1999 through 2006, by two percent per year from 2006 through 2013, and by 14 percent per year from 2013 through 2016. For each year, rates were higher for males than females.\(^\text{25}\)

**Data Source(s):** DRVS, 2015–2019*

**Summary:** Drug-related deaths per 100,000 people remained relatively steady from 2018 to 2019. Adults 26 to 35 years of age had the greatest rate increase from 2018 to 2019. After experiencing a lower rate of substance use and overdose deaths than 36 to 49-year-olds in 2018, those aged 25 to 35 once again observed the highest rate of all age groups in 2019 (63.8 per 100,000).

Figure 58. Substance use and overdose deaths, per 100,000, by age group: 2015–2019*

*2019 results are preliminary

- The second-highest substance use and overdose death rate was among Mainers between the ages of 36 to 49 years old, at 59.9 per 100,000. This was followed by 50 to 64-year-olds (31.3), 18 to 25-year-olds (19.1), those over 65 (5.3), and people under 18 (0.0). Rates for all age groups except Mainers under 18 increased slightly from 2018 to 2019.

Source: DRVS, 2015 to 2019*
Morbidity and Mortality: Rate of Deaths from Chronic Conditions Associated Substance Use

Indicator Description: Every death in Maine has a recorded cause. This indicator examines the rate of chronic diseases commonly associated with substance use, including primary and contributing factors that lead to alcohol-related liver diseases. The rates show all cases where the disease/condition was identified as a factor in the death (either in primary cause or contributing cause). In this case, a rate per 100,000 of the state population is used to compare the prevalence across certain populations.

Why Indicator is Important: Prolonged and lifelong use of substances, including tobacco and alcohol, can often result in chronic health problems later in life. As a consequence of substance use, alcohol cirrhosis-related deaths are considered potentially preventable.

Data Source(s): DRVS, 2015–2019

Summary: In 2019, the rate of alcoholic cirrhosis-related deaths increased by one death per 100,000 people. Deaths related to alcoholic cirrhosis continue to be substantially higher among men than women.

Figure 59. Deaths from alcohol cirrhosis, per 100,000 of the population: 2015–2019*

Source: DRVS, 2015 to 2019

*2019 results are preliminary

- While rates of alcohol cirrhosis deaths are relatively low, an increase from 9.3 per 100,000 residents to 10.3 100,000 residents was seen from 2018 to 2019.
In 2019, deaths related to alcoholic cirrhosis and liver disease were nearly twice as likely among men (13.7 deaths per 100,000) than women (7.0 deaths per 100,000). The rate of male deaths from alcoholic cirrhosis remained stable from 2018 to 2019, while the rate of deaths in females increased by two per 100,000 over the same period.

*2019 results are preliminary
Morbidity and Mortality: Rate of Violent Deaths

Indicator Description: Every death in Maine has a recorded cause. This indicator examines deaths that were the result of violence, i.e., those classified as a suicide or homicide. In this case, a rate per 100,000 of the state population is used to compare the prevalence across certain populations.

Why Indicator is Important: Although not the leading cause of death, substance use and misuse are often factors in homicides and suicides. For example, the federal Substance Abuse and Mental Health Services Administration has estimated that about 47 percent of homicides and 23 percent of suicides are influenced by alcohol nationally.

Data Source(s): DRVS, 2015–2019*

Summary: Suicide rates in Maine are more than 10 times higher than homicide rates. Suicides are more than four times as likely in men compared to women, and most prevalent among adults aged 26 to 34. In addition, deaths due to homicide are slightly more likely among men; rates for homicide are highest among adults between the ages 36 and 49.

Source: DRVS, 2015 to 2019*

*2019 results are preliminary

- There were 20.2 suicides per 100,000 Mainers in 2019 compared to 1.9 homicides per 100,000 residents. Homicide and suicide rates continue to be stable.
In 2017-19, death by suicide was most prevalent in Mainers aged 26 to 35 (26.3 per 100,000). Although not shown, between 2016–18 deaths due to suicide were most prevalent among the 50 to 64-year-old population, followed by Mainers aged 26 to 35.

The age group with the highest prevalence of death by homicide is 36 to 49-year-olds (3.4 per 100,000), followed by 26 to 35-year-olds (2.9 per 100,000).

Deaths by suicide were considerably more prevalent among men in 2017–19 (33.2 per 100,000), compared to women (7.8 per 100,000). Although not shown, there was a slight decrease in female suicide rates and an increase in male suicide rates from 2016–18 to 2017–19.
The homicide rate is much lower than that of suicide but has increased slightly from 2016-18 to 2017–19 for both men and women. The rate for men was slightly higher than the rate for women in 2017-19 at 2.5 per 100,000 and 1.7 per 100,000 respectively.
**Substance Exposed Babies: Babies Born Exposed to/Affected by Substances**

**Indicator Description:** This indicator reflects the number of infants born in Maine where a healthcare provider reported to the Office of Child and Family Services (OCFS) that there was reasonable cause to suspect the baby may be either affected by illegal substance use, demonstrating withdrawal symptoms resulting from prenatal drug exposure (illicit or prescribed), or have fetal alcohol spectrum disorders. This measure potentially excludes instances where the infant was exposed to substances and did not show withdrawal symptoms after birth, instances where the birth of an infant affected by substances was not reported to OCFS, and any other instances in which there were discrepancies between reporters when interpreting the law.\(^{26}\)

**Why Indicator is Important:** Prenatal exposure to alcohol, tobacco, and illicit drugs has the potential to cause a wide spectrum of physical, emotional, and developmental problems for these infants. The harm caused to the child can be significant and long-lasting, especially if the exposure is not detected and the effects are not treated as soon as possible.

**Data Source(s):** OCFS/MACWIS 2015–2019

**Summary:** The number of substance exposed infant notifications has decreased steadily since 2016. In 2019, 858 substance exposed infant notifications were made, which accounts for about seven percent of the live births in Maine that year. From 2016 to 2019, the number of substance exposed infant notifications has decreased by 16 percent.

![Figure 64. Number of substance-exposed infant notifications: 2015–2019](image)

Source: OCFS/MACWIS, 2015 to 2019

- Child Protective Services notifications regarding infants born substance-exposed decreased by 46 (5%), from 2018 to 2019.

\(^{26}\) MRS Title 22, §4011-B; notification of prenatal exposure to drugs or having fetal alcohol spectrum disorders.
From 2017 to 2018, there was no change in the proportion of live births with substance exposed notifications (7.3%). The proportion of live births with substance exposure has decreased slightly since 2016.

Source: OCFS, 2015 to 2019
Factors Contributing to Substance Use and Misuse

Substance use prevention research has identified certain groups of factors that “cause” or have an impact on substance use and the consequences related to use. That is, they appear to influence the occurrence and magnitude of substance use and its related consequences. Generically, these causal factors (also known as contributing factors) are categorized into groups which include:

- **Social Access** *(e.g., getting drugs and alcohol from friends or family)*;
- **Retail Availability** *(e.g., retailer not carding properly, over-prescribing/dispensing, outlet density)*;
- **Pricing and Promotion** *(e.g., two-for-one specials, industry sponsorships or signage)*;
- **Social/Community Norms** *(e.g., parental/community attitudes and beliefs)*;
- **Enforcement** *(e.g., lack of compliance checks, lack of enforcing policies, laws)*;
- **Perceptions of Harm** *(e.g., individuals’ belief that using a substance is harmful)*; and
- **Perceived Risk of Being Caught** *(e.g., individuals’ belief that s/he will be caught by parents or police)*.\(^{27,28}\)

In this report, data are presented on many of these factors particularly as they relate to youth and young adults, parents, and cultural norms. These measures can help prevention professionals make decisions about what types of behaviors, attitudes, and norms should be targeted to prevent substance use and misuse. It also important to think about how these factors are or could be affected by COVID-19. There have been relaxations of liquor regulations and potential changes in parental attitudes as it relates to substance use. With many uncertainties about in-person attendance in school and participation in extracurricular activities, greater attention must be placed on providing youth programming and resources that protect them from substance use.

According to the 2019 Maine Integrated Youth Health Survey (MIYHS), six out of 10 high school students felt it would be easy to obtain alcohol while over one-third of parents reported that their teen could access alcohol in their home without permission. When asked about marijuana, a little over half of students reported that it would be easily accessible if they chose to seek it out.

In contrast to alcohol, according to a survey administered to parents of teens, it is much less common for parents to report that teens have access to drugs *(e.g., marijuana, tobacco)* and/or medication at home. In fact, parents were six times more likely to think their child could access alcohol than substances such as non-prescription pain medications. It is worth noting that in recent years there has been an uptick in the number of teens reporting that they had been sold,\(^ {27}\) Birckmayer, J. D., Holder, H. D., Yacoubian Jr, G. S., & Friend, K. B. (2004). A general causal model to guide alcohol, tobacco, and illicit drug prevention: assessing the research evidence. *Journal of Drug Education, 34*(2), 121–153.\(^ {28}\) Bonnie, R. J. (Ed.). (2004). *Reducing underage drinking: A collective responsibility*. National Academies Press.
offered, or given an illegal drug on school property within the past year. Availability and potential for diversion are major risk factors that affect an individual’s decision to initiate or continue to engage in substance use. With the proliferation of alcohol, marijuana, and vaping products in Maine, it’s important that prevention strategies are geared towards counter-messaging and educating students, their schools, guardians, businesses, and the community at large on the risks associated with easy access and underage substance use.

The volume of prescription drugs dispensed in our state suggests the degree of availability of those drugs in the community. Based on data gathered from Maine’s Prescription Monitoring Program (PMP), the total number of opiate agonist (e.g., pain reliever) prescriptions dispensed in Maine continues to observe a steady decline. Looking at trends among all prescription opiate doses (e.g., pills, patches) dispensed, the most common primary active ingredients are oxycodone, hydrocodone, and tramadol, which together made up three-quarters of the opiate doses dispensed. While pain reliever prescriptions have been curtailed, prescriptions dispensed with the active ingredient of buprenorphine (a partial opiate agonist often used to treat opioid use disorder) have been steadily increasing over the past several years. In addition, prescriptions for sedatives have observed a decrease in recent years, while prescriptions dispensed for stimulants have observed a relatively steady increase. Although the medications mentioned above are designed to help treat those that are suffering from an affliction or disorder, there is still a potential for diversion and misuse; this is why it is imperative that we continue to monitor prescription drug trends and emphasize the importance of diversion control.

Over the past several years, teens’ perceptions of risk associated with alcohol consumption has steadily increased while the perceived risk of marijuana use has continued to fall. Eight out of 10 high school students reported that people risk harming themselves if they binge drink once or twice a week, compared to just one-third of students who thought that there was moderate-to-great risk to using marijuana once or twice a week.

Perception of harm from marijuana use has decreased among parents as well; the perceived overall risk of use of alcohol and especially prescription pain medication for their children was substantially higher than that for marijuana. More than half of parents indicated that their child should not use marijuana because it was unhealthy and about one quarter felt there was a potential for addiction or that there would be a negative impact on their child’s future. Additionally, prevention professionals must pay close attention to our emerging adult population (18–25-year-olds). Young adults in Maine are much less likely to perceive regular or risky substance use as harmful and therefore are more apt to engage in risky substance use. As this population makes the transition into adulthood, we must intentionally strategize to build awareness within this population regarding the dangers and long-term risks of substance use.

Finally, data suggest that certain protective factors such as adequate sleep and strong family and social support may mitigate the risk of substance use behaviors and mental health issues among youth. While the vast majority of high school students still believe that their family has clear rules about alcohol and drug use, many students reported that they would not be caught if they used marijuana or drank alcohol. There continues to be a large discrepancy between what parents
think their child is doing and what their child self-reports; this supports the notion for more intentional communication between children and adults around drug use and health. Prevention strategies should continue to address this discrepancy and embrace interventions and strategies that are focused on fostering relationships as well as strengthening communication and trust.
AVAILABILITY AND ACCESSIBILITY

Availability and Accessibility: *Ease of Obtaining Alcohol by Underage Youth*

**Indicator Description:** This indicator reflects the percentage of high school students (grades 9 to 12) who reported that it would be easy or very easy for them to get alcohol if they wanted some.

**Why Indicator is Important:** High school students who reported that they thought alcohol was easy to obtain were nearly four times as likely to report consuming alcohol within the past month compared to students who did not think it was easy to obtain.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** Six out of 10 high school students think it would be easy to obtain alcohol. The rate of high school students perceiving alcohol as being easily accessible steadily decreased from 2011 to 2017 but has plateaued since.

![Figure 66. High school students who reported it would be easy to get alcohol: 2011–2019](image)

- In 2019, 61 percent of students felt it would be easy for them to obtain alcohol. Overall, this rate has decreased by six percentage points since 2013 (67%).

*Source: MIYHS, 2011 to 2019*
**Availability and Accessibility: Underage Youth Receiving Alcohol from Others**

**Indicator Description:** This measure reflects the percentage of high school students who drank within the past 30 days, reporting that they usually obtain the alcohol they drink from someone giving it to them.

**Why Indicator is Important:** Easy social access to alcohol is a major contributing factor to underage drinking. Students who report that alcohol is easy to get are nearly four times as likely to drink as their peers who report it is not easy.

**Data Source(s):** MIYHS 2011–2019

**Summary:** Social access continues to be a primary way that underage youth obtain alcohol. Of those students who obtained alcohol, over one third reported that someone had given it to them.

![Figure 67. High school students who obtained alcohol by someone giving it to them, among those who drank in past month: 2011–2019](image)

*Source: MIYHS 2011 to 2019*

- In 2019, 36 percent of high school students who obtained alcohol in the past month reported that someone gave them the alcohol they consumed; this represents a decrease of four percentage points since 2015 (40%).
Availability and Accessibility: *Parent Perception of Accessibility of Drugs and Alcohol*

**Indicator Description:** This indicator measures the percentage of parents, (of 7th thru 12th graders) reporting that their teen would be able to access drugs or alcohol at home without their knowledge. These data come from the Maine Parent Survey, administered by Pan Atlantic Research for the Maine Center for Disease Control and Prevention.

**Why Indicator is Important:** Easy access to prescription drugs or alcohol is a major contributing factor to substance use. According to the MIYHS, high school students who perceived prescription medication as easy to obtain were about five times as likely to have misused prescription medication in the past month compared to those who thought that prescription drugs were not easy to obtain.

**Data Source(s):** Parent Survey 2019

**Summary:** In 2019, just over half of parents did not think that their teen could access alcohol, prescription drugs, tobacco, or marijuana in their home without their knowledge. Just over one-third of parents felt their child could access alcohol at home without permission. Parents were six times more likely to feel their child could access alcohol compared to other substances such as non-pain prescription medications or tobacco. Parents are much less likely to feel their teen will access prescription pain medication or marijuana at home (under 4%).

![Figure 68. Substances thought to be accessible by teens without parents' knowledge in the home, by substance type: 2019](image)

*Source: Parent Survey 2019*

- In 2019, about 38 percent of parents reported that their teen would be able to access alcohol without their knowledge, this was followed by prescription drugs other than pain medication (6.2%), tobacco products (5.8%), prescription pain relievers (3.2%) and marijuana at two percent. Just over half (52.8%) of parents thought their teen would not be able to access any of these substances at home without their knowledge.
Availability and Accessibility: *Ease of Obtaining Marijuana by Youth*

**Indicator Description:** This indicator shows the percentage of high school students reporting it would be easy or very easy to obtain marijuana if they wanted it.

**Why Indicator is Important:** According to the MIYHS, high school students who reported that they thought marijuana was easy to obtain were more than nine times as likely to use marijuana in the past 30 days compared to their peers who thought it was difficult to obtain.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, a little over half (53%) of high school students believed that marijuana would be easy or very easy to obtain. This rate has plateaued in recent years.

![Figure 69. High school students who reported it would be easy to get marijuana: 2011–2019](image)

*Source: MIYHS, 2011 to 2019*

- After observing a steady decline from 2011 (57%) to 2017 (52%), the rate of students has remained relatively consistent. In 2019, 53 percent of high school students reported it would be easy to get marijuana.
Availability and Accessibility: Illegal Drugs on School Property

**Indicator Description:** This measure represents the percentage of high school students reporting they were sold, offered or given an illegal drug on school property during the past year.

**Why Indicator is Important:** According to the MIYHS, students who reported they were offered drugs at school were twice as likely to use marijuana as their peers who were not offered drugs at school.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, nearly one in four high school students reported being sold, offered, or given an illegal drug on school property within the past year. This rate has observed an uptick since 2017.

![Figure 70. High school students who were sold, offered, or given an illegal drug on school property in past year: 2011–2019](source: MIYHS, 2011 to 2019)

- After observing a four-point decrease from 2011 (24%) to 2017 (20%), the percentage of high school students who reported they were sold, offered, or given an illegal drug on school property saw an increase of three percentage points. In 2019, 23 percent of Maine high schoolers claimed they were sold, offered or given an illegal drug on school property.
Availability and Accessibility: Prescriptions Dispensed

**Indicator Description:** These indicators reflect the number of opiate agonist*, sedative, and stimulant prescriptions as well as doses dispensed (quantity dispensed) in Maine. These measures reflect prescriptions dispensed to Maine residents only. This is collected through the Maine’s Prescription Monitoring Program (PMP).

**Why Indicator is Important:** The number of prescriptions prescribed indicate the volume of prescription drugs potentially available in the community for diversion (e.g., gift, sale, or theft). A higher level of availability contributes to misuse by individuals without a prescription. More than half of individuals who reported they misused a prescription pain reliever also reported they had received it from a friend or relative for free.²⁹

**Data Source(s):** PMP, 2017–2019

**Summary:** From 2017 to 2019, the number of prescriptions dispensed for opiate agonists (excluding partial agonists such as buprenorphine) decreased by 18 percent and the number of prescriptions for sedatives decreased by nine percent, while prescriptions dispensed for stimulants increased by eight percent. In 2019, just over half of all opiates (agonists as well as partial agonists) dispensed contained the primary active ingredients of either oxycodone or hydrocodone. The proportion of opiate agonists with Buprenorphine has been steadily increasing over the past several years and represents one in eight doses dispensed of all narcotics.

![Graph showing number of prescriptions dispensed in Maine, by type*: 2017–2019](image)

*Opiate analgesics include pain relievers and exclude medicated assisted prescriptions such as buprenorphine. In addition, opiate analgesic in the form of powder were excluded from this analysis.

The number of prescriptions dispensed for opiate agonists (excluding partial agonists used in medicated assisted treatment) decreased by 18 percent from 2017 (873,255) to 2019 while the count of prescriptions dispensed for sedatives decreased by 10 percent from 2017 (709,010) to 2019 (636,076). During the same time frame, prescriptions dispensed for stimulants increased by eight percent (446,355 in 2017 to 480,090 in 2019).

![Figure 72. Percentage of opiates dispensed, by primary active ingredient: 2017–2019*](image)

Source: PMP, 2017 to 2019

The most common active ingredient within all opiate agonists as well as partial agonists doses dispensed since 2017 has been oxycodone, making up 32 percent of doses dispensed in 2019. This is followed by hydrocodone (making up 23 percent of all narcotic doses dispensed), tramadol at 19 percent, and buprenorphine at 13 percent. All primary active ingredients shown, with the exception of buprenorphine, remained relatively constant since 2017. The proportion of buprenorphine doses has increased from eight percent in 2017 to 13 percent in 2019.
Availability and Accessibility: Substances Requested for Verification

Indicator Description: This indicator shows the number of requests by non-law enforcement for medication verification through the Northern New England Poison Center (NNEPC). A person may call the NNEPC for many reasons, one being to help identify a medication or substance which they or another person has consumed or that has been found. The calls reflected in this indicator have been characterized by NNEPC as likely related to substance use, although NNEPC staff do not make a formal or clinical assessment.

Why Indicator is Important: The volume of medication verification calls suggests the degree of availability of those drugs in the community.

Data Source(s): NNEPC, 2017–19

Summary: Most calls to Northern New England Poison Center requesting medication verification in 2017–19 involved opioids, followed by benzodiazepines, and stimulants.

Figure 73. Substances most frequently requested for medication verification by non-law enforcement, by type: 2017–19

- Opioids: 1,053
- Benzodiazepines: 621
- Stimulants/street drugs: 389
- Cardiovascular: 317
- Non-opioid analgesics: 277
- Antidepressants: 189
- Skeletal Muscle Relaxants: 161

Source: NNEPC, 2017 to 19

- During the three-year period of 2017–19, the Poison Center received an average of 1,053 calls per year requesting verification for substances that were identified as opioids, followed by benzodiazepines (621), and stimulant/street drugs (389). Although not shown, the volume of calls for these substances has decreased steadily since 2010; according to the NNEPC, this can partly be attributed to callers transitioning to online research, which has not been tracked, or the decrease in the number of prescriptions written.
Perceived Harm: Perceived Risk from Regular Alcohol Use

**Indicator Description:** This indicator reflects the percentage of high school students who report that there is moderate to great risk of harm from drinking one or two alcoholic beverages every day.

**Why Indicator is Important:** High school students who do not perceive regular alcohol use (one to two drinks per day) as risky were almost twice as likely to drink in the past month than students who did perceive harm.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, six out of 10 high school students think there is moderate-to-great risk of harm from drinking alcohol regularly (one to two drinks every day); this has remained relatively stable since 2011.

*Figure 74. High school students perceiving moderate to great risk from drinking 1–2 drinks every day: 2011–2019*

Source: MIYHS, 2011 to 2019
**Perceived Harm: Perceived Risk from Binge Drinking**

**Indicator Description:** This indicator reflects the percentage of individuals (high school students and adults) who perceive that there is moderate-to-great risk from drinking five or more drinks in a row once or twice per week.

**Why Indicator is Important:** According to MIYHS, high school students who did not perceive a moderate-to-great risk of harm from binge drinking once or twice a week were twice as likely to drink in the past month as high school students who did perceive risk of harm. Perceptions around the risks of binge drinking are related to high-risk alcohol use among adults as well.

**Data Source(s):** MIYHS, 2011–2019; NSDUH 2016–17 and 2017–18

**Summary:** Four out of five high school students (82%) think binge drinking once or twice a week is harmful. Perception of harm from binge drinking remains much lower among young adults. More than seven out of 10 young adults (18 to 25) thought that binge drinking a few times a week was not risky.

*Figure 75. High school students perceiving moderate to great risk from drinking five or more drinks once or twice per week: 2011–2019*

- In 2019, 82 percent of Maine High school students reported that they perceived drinking five or more drinks in one sitting once or twice a week as a moderate to great risk. Perception of risk associated with binge drinking has remained relatively steady from 2011 to 2019.

*Source: MIYHS, 2011 to 2019*
Forty-one percent of Mainers ages 26 and older reported that drinking five or more drinks once or twice per week posed some risk of harm in 2017–18, a decrease from 2016–17 (42%). Perception of harm from binge drinking was consistently lower among 18 to 25-year-olds in 2017-18 at 29 percent, which is consistent with 2016–17.

Source: NSDUH 2016–17 and 2017–18
**Perceived Harm: Perceived Risk of Regular Marijuana Use**

**Indicator Description:** This measure demonstrates the percentage of individuals (high school students and adults) who perceive a moderate-to-great risk of harm from smoking marijuana once or twice per week.

**Why Indicator is Important:** High school students who do not believe there is moderate-to-great risk in smoking marijuana regularly are almost seven times as likely to smoke marijuana as their peers who do perceive risk of harm. In addition to the risk of developing a marijuana use disorder (MUD) and using other illegal substances, research has indicated significant associations between adolescent marijuana use and poor social and educational development and functioning, as well as having other mental health problems. In addition, adverse consequences of marijuana use can extend into adulthood, including substance use and misuse, cognitive impairment, criminal justice involvement, and ongoing mental and physical health problems.³⁰

**Data Source(s):** MIYHS, 2013–2019; NSDUH, 2012–13 to 2017–18

**Summary:** In 2019, one-third of high school students felt using marijuana once or twice a week was risky. In 2017–18, six percent of 18 to 25-year-olds perceive smoking marijuana at least once per month as risky. Perceptions of harm regarding marijuana use have decreased among both youth and adults over the past several years.

![Figure 77. High school students perceiving moderate-to-great risk from using marijuana once or twice a week: 2013-2019*](source)

*Source: MIYHS, 2013 to 2019

*Question changed in 2017 from asking about “smoking marijuana” to “using marijuana”

---

The proportion of high school students who perceived a moderate-to-great risk of harm from using marijuana once or twice a week has declined by nine percentage points from 2013 to 2019. In 2019, one-third (33%) of high school students thought that using marijuana once or twice per week was risky. Inversely, this implies that 67 percent of students thought that it was not risky to do so.

**Figure 78.** Adults (age 18 and older) perceiving great risk from smoking marijuana once per month, by age group: 2012–13 to 2017–18

Source: NSDUH, 2012–13 to 2017–18

In 2017–18, young adults 18 to 25 were unlikely to perceive a great risk from smoking marijuana at least once per month (6%), whereas Mainers who were 26 years old or older had a higher perception of risk (18%). Both age groups’ perception of risk has slightly decreased from 2016–17.
**Perceived Harm: Perceived Risk of Prescription Drug Misuse**

**Indicator Description**: This measure demonstrates the percentage of high school students who perceive a moderate to great risk of harm from taking a prescription drug that was not prescribed to them.

**Why Indicator is Important**: Factors such as perception of harm from using a substance can have a significant impact in determining whether an individual will initiate use. It is important that youth are taught at a young age of the harms and risks (e.g., addiction) associated with misuse of prescription drugs.

**Data Source(s)**: MIYHS, 2015–2019

**Summary**: In 2019, the vast majority of high school students (88%) reported that it would be harmful if they took a prescription drug that was not prescribed to them. Female students were more likely to perceive a risk than males; 90 percent compared to 86 percent, respectively.

![Figure 79. High school students who felt using a prescription drug not prescribed to them was harmful, by age group: 2015–2019](image)

*Source: MIYHS, 2015 to 2019*

- In 2019, 88 percent of Maine high school students reported that they believed it would be harmful if an individual took a prescription drug that was not prescribed to them. When broken out by gender, females were more likely to perceive a risk than males; 90 percent compared to 86 percent, respectively.
**Perceived Harm: Perceived Risk of Heroin Use**

**Indicator Description:** This measure demonstrates the percentage of individuals (youth and adults) who perceive a moderate to great risk of harm from trying heroin once or twice.

**Why Indicator is Important:** Factors such as perception of harm from using a substance can have a significant impact in determining whether an individual will initiate use. It is important that youth are taught at a young age of the harms and risks (e.g., addiction) associated with opioid use.

**Data Source(s):** NSDUH, 2017–18

**Summary:** In 2017–18, nearly nine out of 10 adults reported that trying heroin once or twice was of moderate-to-great risk. Youth aged 12 to 17 were much less likely to perceive a risk. About two-thirds of 12- to 17-year-olds thought there was great risk from trying heroin once or twice.

![Figure 80. Mainers perceiving great risk from trying heroin once or twice, by age group: 2017–18](image)

*Source: NSDUH, 2017–18*

- In 2017-18, 65 percent of 12 to 17-year-olds, 84 percent of 18 to 25-year-olds, and 89 percent of Mainers aged 26 and older reported that trying heroin once or twice was of moderate-to-great risk. Although not shown, these rates show a slight decrease in perception of risk in 12 to 17-year-olds and 18 to 25-year-olds from 2016–17.
**Perceived Harm: Parent Perceived Risk of Child’s Substance Use**

**Indicator Description:** This measure demonstrates the percentage of parents of 7th thru 12th graders who perceive a moderate to great risk of harm from their child using substances regularly.

**Why Indicator is Important:** Factors such as perception of harm from using a substance can have a significant impact in determining whether an individual will initiate use. It is important that youth are taught at a young age of the harms and risks of substance use.

**Data Source(s):** Parent Survey 2019

**Summary:** For parents, the perceived overall risk of use of alcohol and especially prescription pain medication for their children was substantially higher than that for marijuana. In 2019, only half of parents surveyed felt using marijuana on weekly basis would be harmful.

**Figure 81. Parents perception of risk from child’s substance use, by type: 2019**

- 94% Ever misusing prescription pain medication
- 80% 1 or 2 alcoholic drinks every day
- 52% Marijuana once or twice per week

*Source: Parent Survey, 2019*

- In 2019, 94 percent of parents of 7th through 12th graders reported that they felt it would be risky if their child ever misused prescription pain medication, 80 percent agreed it would be a moderate-to-great risk for their child to consume one or two drinks every day, and just over one-half (52%) believed using marijuana once or twice per week would be harmful.
**PERCEIVED ENFORCEMENT**

**Perceived Enforcement: Youth Perceived Risk of Being Caught Drinking Alcohol**

**Indicator Description:** This indicator shows the percentage of high school students perceiving they would be caught by their parents or by police if they drank alcohol.

**Why Indicator is Important:** According to the MIYHS, high school students who believed they would not be caught by their parents were more than five times as likely to drink in the past month, compared to students who did think they would be caught. In addition, students who believe that they would not be caught by the police were three times as likely to drink alcohol in the past month as those who did think they would be caught.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, half of high school students thought they would be caught by their parents for drinking alcohol while 18 percent felt they would be caught by the police. Perceptions of getting caught by parents or police decreased from 2017 to 2019.

*Figure 82. High school students reporting they would be caught by parents or the police if they drank in their neighborhood: 2011–2019*

*Source: MIYHS, 2011 to 2019*
Perceived Enforcement: Youth Perceived Risk of Being Caught Smoking Marijuana

Indicator Description: This indicator represents the percentage of high school students perceiving they would be caught by police if they smoked marijuana.

Why Indicator is Important: According to the MIYHS, high school students who believed they would not be caught by the police (for smoking marijuana in their neighborhood) were almost five times as likely to smoke marijuana as their peers.

Data Source(s): MIYHS, 2011–2019

Summary: In 2019, 22 percent of high school students thought they would be caught by police in their neighborhood for using marijuana. Therefore, the majority of high school students were not worried about being caught by the police for using marijuana. Rates have remained relatively stable since 2013.

Source: MIYHS, 2011 to 2019

*In 2017, the indicator changed from “smoking” marijuana to “using” marijuana
**Community and Cultural Norms: Youth Perception of Parental Attitudes Toward Alcohol Use**

**Indicator Description:** This indicator depicts the percentage of high school students who thought that their parents feel it would be wrong for them to drink regularly. It also examines the proportion who reported that adults in their community think it would be wrong for kids their age to consume alcohol.

**Why Indicator is Important:** According to the MIYHS, high school students who did not believe their parents felt it would be wrong for them to drink were more than twice as likely to drink alcohol in the past month as their peers who did think their parents would perceive it as wrong.

**Data Source(s):** MIYHS, 2015–2019

**Summary:** High school students largely believe that their parents and adults in their community think it would be wrong for them to drink alcohol. In 2019, more than nine out of 10 students perceived that their parents would think it was wrong for them to use alcohol regularly. This was compared to three out of four students who felt that adults in their community would think it was wrong. The perception of disapproval remained stable in both parents and adults in the community from 2017 to 2019.

![Figure 84. High school students who reported perceiving that their parents and adults in their community think student alcohol use is wrong: 2015–2019*](image)

*Source: MIYHS, 2015 to 2019*

- The proportion of high school students who thought their parents felt it would be wrong for them to drink one to two drinks per day increased one percentage point from 2017 (93%) to 2019 (94%).
- In 2019, 73 percent of students reported that adults in their community think it is wrong for youth to use alcohol. This has remained unchanged since 2015.
Community and Cultural Norms: Youth Perception of Parent Attitudes Toward Marijuana Use

**Indicator Description:** This indicator shows the percentage of high school students who reported that their parents feel it would be wrong for them to smoke marijuana.

**Why Indicator is Important:** According to the MIYHS, high school students who don’t believe their parents feel it is wrong for them to smoke marijuana are four times as likely to use marijuana as students who believe their parents think it is wrong.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** Although high school students generally believe that their parents think it would be wrong for them to use marijuana; perceptions of disapproval have gradually decreased from 2011 (84%) to 2019 (80%). One in five high school students felt their parents would not disapprove of them using marijuana.

*Source: MIYHS, 2011 to 2019

*In 2017 this indicator changes from “smoked” marijuana to “used” marijuana*
Community and Cultural Norms: Parental Attitudes Regarding Marijuana Use

Indicator Description: This indicator reflects how parents felt about their teen using marijuana. Maine parents of teenagers (7th to 12th graders) were asked to select the response that best described their attitude about marijuana use by their child. Response options were mutually exclusive. These data come from the Maine Parent Survey, administered by Pan Atlantic Research for the Maine Center for Disease Control and Prevention.

Why Indicator is Important: Parental perceptions and permissive attitudes towards substance use can have a major effect in their child’s decision to use. As Maine observes changes in regulations and policies regarding marijuana use; changes to cultural norms and beliefs around use are occurring as well.

Data Source(s): Parent Survey 2019

Summary: Over half of parents of 7th through 12th graders cited that their child should not use marijuana because it was unhealthy. About one in four parents felt there was a potential for addiction or that there would be a negative impact on their child’s future. Nearly one-fifth of parents believed that marijuana use among their teens could potentially cause legal problems. Two percent of parents felt it was okay for their teen to use marijuana.

Figure 86. Parent’s top reasons for their teen not to use marijuana: 2019

- In 2019, the most commonly cited reason from parents as to why their teen should not use marijuana was that it was unhealthy (55%); this was followed by potential for addiction (27%), negative impact on child’s future (23%), potential legal problems (18%), teen was too young to use (12%), marijuana use could lead to other substance use (12%), and it was against family values (8%). Two percent of parents surveyed felt it was okay for their teen to use marijuana.
**Community and Cultural Norms: Youth Perception of Family Rules Toward Substance Use**

**Indicator Description:** This indicator reflects the percentage of high school students who reported that their family has clear rules about the use of alcohol, tobacco and other drugs (substance use).

**Why Indicator is Important:** According to the MIYHS, high school students who believe their parents have clear rules about substance use are half as likely as their peers to drink alcohol.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, nine out of 10 high school students reported that their family has clear rules around substance use. However, one in 10 students still did not think their family had clear rules and were therefore at higher risk for underage alcohol use than their peers. Rates of perception of clear rules around substance use had been steadily increasing since 2011 but decreased slightly in 2019.

![Figure 87. High school students who reported their family has clear rules about alcohol and drug use: 2011–2019](image)

*Source: MIYHS, 2011 to 2019*

- High school students who agreed their family has clear rules about the use of alcohol, tobacco and other drugs increased by five percentage points from 2011 (85%) to 2019 (90%).
Community and Cultural Norms: Parent Perception of Child’s Substance Use

Indicator Description: This indicator reflects the percentage of parents who perceived that their child (7th through 12th graders) was using substances.

Why Indicator is Important: Parental perceptions of child behaviors compared to the actual behaviors reported by youth often differ from one another. This disconnect can be challenging to reconcile, especially when confronting youth substance use and parental monitoring.

Data Source(s): Parent Survey, 2019

Summary: In 2019, nearly one in 10 (8.2%) parents of 7th thru 12th graders thought their teen had used a vapor product within the past 30 days. One in twenty parents thought their child had used marijuana and four percent believed their teen had drank any alcohol. Furthermore, only 0.2 percent of parents surveyed thought that their teen had misused a prescription pain medication in the past 30 days.

![Figure 88. Parent’s perception of child’s substance use within the past 30 days, by substance type: 2019](image)

Source: Parent Survey, 2019

- In 2019, 8.2 percent of parents of 7th thru 12th graders believed their teen had used a vapor product in the past 30 days; this was followed by marijuana (5.3%), alcohol (3.8%), any tobacco product (3.2%), and prescription pain medication (0.2%).
Impact of Protective Factors on Substance Use and Mental Health: Protective Factors Among Youth

Indicator Description: This indicator explores the extent to which protective factors or behaviors influence substance use and mental health among youth.

Why Indicator is Important: There are some protective factors, like sleep, social support, and familial support, that taken together may mitigate the risk of substance use behaviors and mental health issues among youth.

Data Source(s): MIYHS, 2019

Summary: The prevalence of substance use, suicide ideation and feelings of sadness and helplessness are higher among high school students who report certain risk factors. Teens who had less than eight hours of sleep were twice as likely to experience feelings of depression or suicide ideation. In addition, teens are much more likely to report feelings of sadness and helplessness, as well as substance use and suicide ideation if they don’t feel that they matter to their community, have three or more adverse childhood experiences, or report that their parents don’t know where they are when not at home.

Source: MIYHS, 2019

- High school students reporting sleeping more than eight hours on average during school nights were less likely to drink alcohol (16% versus 26% of those who did not get a full night’s rest), feel sad or helpless (19% versus 35%), or seriously consider suicide (8% compared to 19%) compared to those who sleep less than eight hours.
Figure 90. Alcohol use, feelings of sadness and suicide ideation among youth who feel like they matter to people in the community and those who do not: 2019

![Graph showing alcohol use, feeling sad or helpless, and seriously considered suicide for youth who matter vs. those who don’t matter.]

Source: MIYHS, 2019

- High school students who felt like they mattered to their community reported less alcohol use, feelings of depression, and suicidal consideration. While the difference in alcohol use was relatively small, youth who said they felt like they do not matter were two to three times more likely to have thoughts and feelings associated with depression as well.

Figure 91. Past-month high school substance use by whether or not their parents know where they are when not at home: 2019

![Graph showing past-month substance use by parents' knowledge of where students are when not at home.]

Source: MIYHS, 2019
• High school students who felt their parents or guardians did not know where they are most or all the time when they are not at home were more likely to use substances in the past month. Youth who think their parents do not know where they are were more than five times as likely to have misused prescription drugs and nearly four times as likely to have smoked cigarettes.

• Although not pictured, high school students who felt that they had a parent or guardian that tries to help them succeed were also two to three times less likely to have used alcohol, marijuana, prescription drugs, and cigarettes within the past month. Additionally, this is also true of students who believe their family loves and supports them.

Figure 92. Alcohol use, feelings of sadness and suicide ideation among youth based on the number of adverse childhood experiences reported: 2019

Source: MIYHS, 2019

• High school students who reported three or more adverse childhood experiences (ACEs) reported greater alcohol use, feeling sad or helpless, and serious suicidal consideration when compared to those who reported fewer ACEs. Those who reported having one or two ACEs were more likely to report alcohol use, feeling sad or helpless, and serious suicidal consideration than those who did not report any ACEs.
Mental Health, Suicide and Co-occurring Disorders

The relationship between substance use and mental health has been well documented. At the individual level, it is important to know if one exists because the symptoms of each can affect the other; for example, a person who is depressed may use alcohol to feel better. At the community level, it is important to understand how the prevalence of one interacts with the other so that prevention and intervention efforts can better address the needs of both. The data indicators included below represent multiple mental health indicators that can be routinely monitored in relation to substance use, in hopes that this will lead to a better understanding of co-occurring disorders and the prevention and intervention initiatives needed to address them. As was mentioned earlier, monitoring mental health issues is essential during the COVID-19 pandemic. Effective data collection helps the state of Maine to be proactive rather than reactive in this unprecedented situation. The SEOW will track mental health diagnoses in the coming years to determine the impact this pandemic has and will have on Mainers.

According to most recent estimates, roughly one-fifth of adults experienced any mental illness in the past year. Specifically, about one in five adults in Maine reported having ever been diagnosed with anxiety, while one in four reported having ever been diagnosed with depression. Rates of depression are consistent among adults ages 18 to 25, 26 to 35, and 36 to 49. Rates of anxiety are highest among adults between 26 and 35 years old. Young adults (aged 18 to 25) are more likely to report experiencing at least one major depressive episode within the past year (about one in six) compared to those over age 25. Rates of depression among young Mainers in high school continue to increase, with about one in three high school students reporting feeling so sad or helpless for at least two weeks in the past year that they stopped doing their usual activities. About one in seven high school students in Maine had planned for suicide, and nearly one in 10 reported they had attempted suicide in the past year. As discussed in the contributing factors section, certain protective factors are more common among teens who do not report suicidal thoughts.

Mental illness has commonly been stigmatized by society. With more Mainers reporting mental health issues, it is imperative that work be done to destigmatize mental health challenges and advocate for getting help when it is needed. Interestingly, 2-1-1 Maine referral calls related to substance use decreased by about one-fifth from 2018 to 2019, while calls related to mental health services increased. In addition, calls regarding housing and shelter increased substantially from 2018 to 2019. Calls to 2-1-1 Maine may fluctuate due to whether or not Mainers are aware of the service.

Comorbidity of substance use and mental illness is common. In 2019, high schoolers who reported drinking in the past month were more prone to have thoughts of suicide when compared to their peers who did not consume alcohol, which is consistent with previous years. One in four high school students who had consumed alcohol in the past month also had serious thoughts of suicide within the past year, compared to one in eight who had not consumed alcohol. Individuals presenting with either mental illness or risky substance use should be
screened for comorbidities to be sure they are directed to appropriate services. It is crucial that we better integrate mental health promotion alongside substance use prevention.
Mental Illness, Depression and Anxiety: Mental Illness and Depressive Episodes Among Adults

Indicator Description: This indicator reflects the percentage of Maine residents age 18 and older reporting experiencing any mental illness, serious mental illness or having experienced at least one major depressive episode.\(^{31}\)

Why Indicator is Important: Experiencing a mental illness or psychological distress in the past year has been associated with higher rates of substance use.

Data Source(s): NSDUH, 2015–16 to 2017–18

Summary: More than one in five adults in Maine reported experiencing any mental illness in the past year. Adults between 18 and 25 years old reported the highest rates of past-year major depressive episodes at 17 percent; an increase of two percentage points since 2016–17.

Figure 93. Adults (age 18 and older) experiencing any mental illness in past year, by age group: 2015–16 to 2017–18

- In 2017–18, 21 percent of adults ages 18 and over, 31 percent of adults between 18 and 25 years old, and 19 percent of adults 26 and older report that they have experienced any mental illness in the past year. These rates have all increased since 2016–17.

---

\(^{31}\) Any mental illness is a diagnosable mental, behavioral, or emotional disorder, other than a substance use disorder, that met the criteria found in the 5th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-V). Serious mental illness is a diagnosable mental, behavioral, or emotional disorder, other than a developmental or substance use disorder, that met the DSM-IV criteria and resulted in serious functional impairment. Major depressive episode is defined as a period of at least two weeks when a person experienced a depressed mood or loss of interest or pleasure in daily activities and had a majority of specified depression symptoms.
In 2017–18, major depressive episodes\(^{32}\) continue to be more prevalent among young adults ages 18 to 25 (17%) compared to adults 26 and older (7%). Major depressive episode rates among both age groups have increased since 2016–17.

\(^{32}\) Major depressive episode (MDE) is defined as in the 5th edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-V), which specifies a period of at least two weeks when a person experienced a depressed mood or loss of interest or pleasure in daily activities and had a majority of specified depression symptoms.
Mental Illness, Depression and Anxiety: Diagnosis of Anxiety and Depression Among Adults

**Indicator Description:** This indicator examines the percentage of Maine residents age 18 and older who have been told they have a depression or anxiety disorder.

**Why Indicator is Important:** The link between mental health and substance use is well documented. Experiencing anxiety or depression in the past year is associated with higher rates of substance use.

**Data Source(s):** BRFSS, 2013–15 to 2015–17

**Summary:** In 2015–17, nearly one in four adults in Maine reported having ever been diagnosed with depression compared to one in five reporting to have ever been diagnosed with anxiety. Rates of depression have been relatively stable since 2013–15. However, rates of anxiety among adults has increased slightly among most age groups.

Figure 95. Adults who have been told they have a depressive disorder by age group: 2013–15 to 2015–17*

*2017 BRFSS estimates are preliminary.

- In 2015–17, about one quarter (24%) of adults in Maine reported having ever been diagnosed with a depressive disorder.
Figure 96. Adults who have been told they have an anxiety disorder by age group: 2013–15 to 2015–17*

Source: BRFSS 2013–15 to 2015–17
*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.

- In 2015–17, approximately one in five (21%) adults in Maine reported having ever been diagnosed with an anxiety disorder. The rate was highest among 26 to 35-year-olds, at 31 percent.
Mental Illness, Depression and Anxiety: Depression Among Youth

Indicator Description: This indicator measures the percentage of high school students reporting they felt sad or hopeless almost every day for two weeks in a row during the past year.

Why Indicator is Important: Experiencing depression in the past year is associated with higher rates of substance use and suicide. High school students who reported feeling hopeless or sad for at least two weeks within the past twelve months were almost twice as likely to have used marijuana or to have engaged in alcohol use in the past 30 days, and three times as likely to have misused prescription drugs during the past 30 days. Among youth, depression is also associated with problems with relationships and academic achievement.

Data Source(s): MIYHS 2011–2019

Summary: In 2019, nearly one in three (32%) high school students felt so sad or helpless for at least two weeks in the past year that they stopped doing their usual activities. There was a five-percentage point increase from 2017 to 2019. Rates of hopelessness among high students in Maine have been steadily increasing since 2011.

Figure 97. High school students who reported feeling sad or hopeless in past year: 2011–2019

Source: MIYHS 2011 to 2019

- The percentage of Maine high school students who reported feeling sad or helpless for at least two weeks in the past year steadily increased from less than one quarter (23%) in 2011 to nearly one third (32%) in 2019.

**Suicidal Ideation: Suicidal Ideation Among Youth**

**Indicator Description:** This measure examines the percentage of high school students who reported that they seriously considered attempting suicide, planned about how they would attempt suicide, or attempted to commit suicide during the past year.

**Why Indicator is Important:** Suicide is the most extreme consequence of major depressive disorders. Use of alcohol or other drugs may increase emotional problems leading to suicidal ideation and suicidal behavior.

**Data Source(s):** MIYHS 2011–2019

**Summary:** In 2019, 16 percent of Maine high school students seriously considered suicide and 13 percent had planned for suicide; rates have increased slightly from 2017. The percentage of students who reported that they had attempted suicide increased from 2017 (7%) to 2019 (9%).

![Figure 98. High school students who considered, planned, or attempted suicide in past year: 2011–2019](source: MIYHS 2011 to 2019)
Mental Health and Substance Use Co-Occurrence: Co-occurring Substance Use and Suicidal Behavior Among Youth

**Indicator Description:** This indicator explores the relationship between alcohol use within the past 30 days and suicidal behavior. It reflects the likelihood of high school students to report that they planned or attempted suicide during the past year by whether they reported consuming alcohol in the past month.

**Why Indicator is Important:** The link between mental health and substance use is well documented. Alcohol is a depressant and its use by depressed individuals may increase suicidal behavior.

**Data Source(s):** MIYHS, 2011–2019

**Summary:** In 2019, the percentage of high school students who had consumed alcohol in the past month and had serious thoughts of suicide within the past year is just over one in four (26%); this is double the rate compared to students who did not drink.

*Figure 99. High school students reporting seriously considering suicide in the past year, by alcohol use in the past month: 2011–2019*

Source: MIYHS 2011 to 2019
Mental Health and Substance Use Co-Occurrence: Information Calls for Mental Health and Human Services

Indicator Description: 2-1-1 Maine is a telephone and internet service that provides information and referrals to health and human services. This indicator reflects the number of calls received by 2-1-1 Maine by the type of service requested.

Why Indicator is Important: The data collected from each call provide valuable information, serving as a barometer of health and human service needs in the state.

Data Source(s): 2-1-1 Maine, 2015–2019

Summary: 2-1-1 Maine referral calls related to housing/shelter outnumbered calls related to mental health services as well as substance use in 2019. Referral calls for housing/shelter, mental health, and gambling observed increases from 2018 to 2019, while calls related to substance use have decreased.

Source: 2-1-1 Maine, 2015 to 2019

- In 2019, there were 5,151 calls to 2-1-1 Maine relating to requests for housing/shelter, followed by 3,160 calls for mental health services, substance use (1,652), and problem gambling (90). The number of 2-1-1 Maine referral calls for mental health services increased by eight percent from 2018 to 2019. Over the same period, housing/shelter calls increased by 44 percent, calls for substance abuse services decreased by 21 percent, and calls related to problem gambling increased by 11 percent.
Primary Treatment Admissions: *Primary Treatment Admissions by Substance*

**Indicator Description:** This indicator reflects substance use treatment admissions in which a substance was listed as the primary reason for admission. The following analysis excludes admissions for shelter/detoxification services as well as those who were identified as co-affected or codependents (e.g., spouse, child, sibling) of the client receiving treatment. The following data include duplicate admissions, meaning that a unique individual/client could be counted multiple times if they were admitted more than once during the year.

**Why Indicator is Important:** The number of substance use treatment admissions is bound by both the need and the capacity for treatment. Therefore, treatment admissions data do not provide a complete indication of substance use, misuse or dependence. They do, however, provide an indication of service usage and impact of substance use on the behavioral healthcare system.

**Data Source(s):** WITS, 2014–2018

**Summary:** Nearly four in 10 substance use treatment admissions listed alcohol as the primary reason for treatment in 2018, followed by heroin/morphine, and other opiates/synthetics. In 2018, nearly half (47%) of primary admissions were related to either opioids or opiates which is consistent with previous years. The proportion of primary admissions related to synthetic opiates continues to decrease as primary admissions involving heroin/morphine continue to increase.

*Figure 101. Number and percentage of primary treatment admissions, by substance type: 2018*

*Source: WITS, 2018*

*WITS system is not static; therefore, 2018 numbers may be lower than true counts. Data were retrieved 7/25/2019*
In 2018, there were a total of 8,543 primary admissions. Of those admissions, 3,336 (39%) were related to alcohol, followed by heroin/morphine (2,673, 32%), other opiates and synthetics (1,278, 15%), marijuana/hashish/THC (442, 5%), cocaine/crack (414, 5%), and methamphetamine (119, 2%).

*Source: WITS, 2014–2018*

- The proportion of primary admissions related to heroin/morphine has increased by eight percentage points from 2014 (23%) to 2018 (31%). During the same time frame, primary admissions related to synthetic opiates decreased by 13 percentage points, from 28 percent in 2014 to 15 percent in 2018.
- Primary admission rates involving alcohol have consistently held the greatest proportion over the past several years. The percentage of primary admissions attributed to cocaine/crack as well as marijuana have been relatively consistent.
Secondary Treatment Admissions: Secondary Treatment Admissions by Substance

Indicator Description: This indicator reflects substance use treatment admissions in which a substance was listed as the secondary reason for admission. Not every admission includes a secondary reason or substance. The following analysis excludes admissions for shelter/detoxification services as well as those who were identified as co-affected or codependents (e.g., spouse, child, sibling) of the client who was receiving treatment. The following data include duplicate admissions, meaning that a unique individual/client could be counted multiple times if they were admitted more than once during the year.

Why Indicator is Important: The number of substance use treatment admissions is bound by both the need and the capacity for treatment. Therefore, treatment admissions data do not provide a complete indication of substance use, misuse or dependence. They do, however, provide an indication of service usage and impact of substance use on the behavioral healthcare system.

Data Source(s): WITS, 2014–2018

Summary: Out of the admissions that listed a secondary substance, nearly one in three was related to marijuana and about one in five was related to synthetic opiates. Rates related to synthetic opiates have steadily decreased while rates involving cocaine/crack have gradually increased.

Source: WITS, 2018

*WITS system is not static; therefore, 2018 numbers may be lower than true counts. Data were retrieved 7/2019
• In 2017, there were a total of 5,414 admissions that listed a secondary substance or reason for treatment. Of those admissions, 1,642 (31%) were related to marijuana, followed by cocaine/crack (837, 20%) and other opiates and synthetics (1,035, 19%).

Source: WITS, 2013 to 2017

• Marijuana/hashish/THC still has the highest proportion of admissions where a secondary substance was listed. The proportion of admissions related synthetic opiates continue to decline while the proportion of admissions related to cocaine/crack has gradually increased.
Treatment Admissions Among Pregnant Women: Substance Use Treatment Admissions While Pregnant

Indicator Description: This indicator explores the primary substances for which pregnant women sought treatment. The following analysis excludes admissions for shelter/detoxification services as well as those who were identified as co-affected or codependents (e.g., spouse, child, sibling) of the client receiving treatment. In addition, the following data analysis includes duplicate admissions, meaning that a unique individual/client could have been counted multiple times if they were admitted during the year on more than one occasion.

Why Indicator is Important: Exposure to alcohol and drugs damage a fetus during all stages of pregnancy. Babies born to mothers who used drugs during pregnancy are at greater risk of experiencing long-term behavioral difficulties and developmental delays. The American Academy of Pediatrics recommends complete abstinence from alcohol and drugs for pregnant women. However, medical professionals advise pregnant women suffering from addiction to seek treatment rather than attempt to quit without medical supervision.

Data Source(s): WITS, 2014–2018

Summary: In 2018, three-quarters of primary pregnant substance use treatment admissions were related to opioids/opiates. In recent years, the percentage of pregnant treatment admissions primarily due to other synthetic opioids has steadily declined while the proportion related to heroin has increased. The proportion of pregnant women seeking treatment primarily for alcohol has increased steadily in recent years.

---

In 2018, 47 percent of pregnant women were seeking treatment primarily for heroin/morphine, followed by other opiates (24%), alcohol (12%), marijuana (5%), cocaine/crack (4%), and methadone (4%), as the primary reason.

The proportion of pregnant women who were admitted for treatment primarily due to other synthetic opiates has been declining since 2014, from 54 percent to 24 percent. Over the same period, the proportion of pregnant women admitted for heroin increased from 26 percent in 2014 to 47 percent in 2018.

The proportion of pregnant women seeking treatment primarily for alcohol increased steadily from 2016 (7%) to 2018 (12%).
Conclusion

Data in this report should be considered as “information for action.” Magnitude, readiness, political will, capacity, and changeability must all be taken into consideration when deciding where efforts should be focused. The surveillance data presented helps us to identify and prioritize the substance use problems present within our state and communities, clarify the impact of these problems on our residents, identify the specific factors that contribute to these problems, assess the readiness and resources needed to address these factors, and evaluate the effectiveness of interventions. Together these data can better convey the prevalence and need for substance use prevention, treatment, and recovery services in our communities and guide data driven decision making. Given that COVID-19 may have a long-lasting impact on substance use as well as mental health in Maine, the Maine State Epidemiological Outcomes Workgroup (SEOW) will continue to track and monitor substance use and behavioral health trends within the context of the current pandemic. Effective and timely data collection along with critical analyses and thoughtful dissemination will help Maine to be proactive rather than reactive in this unprecedented situation.

In regard to the consumption of substances, alcohol continues to be the substance most often used by Mainers across the lifespan, especially among our youth and young adults. Tobacco smoking rates have progressively declined among younger populations while use among older Mainers remains somewhat consistent. In recent years we have observed that the traditional use of tobacco has been replaced by alternative modes. There has been a substantial increase in the initiation and use of electronic vapor products across nearly all age ranges. This influx has precipitated the need for additional education and intervention efforts. Due to policies and strategies designed to curtail supply and diversion, prescription pain reliever misuse among Mainers has decreased substantially over the past several years. However, this has led to an increased demand and supply for more volatile illicit opioids such as heroin and illicitly manufactured fentanyl. In addition, according to recent public health surveillance data, stimulant use/misuse is on the rise in our state and deserves immediate attention.

Data and research affirm that individuals, families, and our communities all suffer the consequences of substance use in terms of increased health care need, criminal justice involvement, and overall strained resources. The opioid epidemic remains to be one of the more complex public health crises of our time and will likely be exacerbated due to the current COVID-19 pandemic. After seeing some relief in terms of mortality from illicit drugs in 2018, there has been another increase. Illicitly manufactured non-pharmaceutical fentanyl continues to be the major driver in drug-related overdose deaths. As for other substances, risky alcohol use continues to have detrimental effects on the health, safety, and well-being of Mainers. Furthermore, drugs such as crystal methamphetamine, cocaine, and other potentially addictive and dangerous prescription drugs (e.g., benzodiazepines, stimulants) have also had a progressively negative impact in Maine. Nearly one-third of drug-related overdose deaths involved either alcohol or stimulants. As Maine and the nation grapple with the persisting opiate/opioid epidemic, it is crucial we monitor other emerging trends and adapt existing strategies to encompass other substances.
Data supports the notion that availability and potential for diversion are major factors that can influence an individual’s decision to initiate or continue to engage in substance use. With the proliferation of alcohol, marijuana, and vaping products in Maine, it’s important prevention strategies are geared towards counter messaging and educating youth, their schools, guardians, businesses, and their communities about the risks associated with accessibility and underage substance use. Confounding factors such as the shifting landscape of Maine’s laws and regulations regarding the medicinal and adult use of marijuana continue to have a profound impact on demand, availability, and perceptions of risk. Therefore it is imperative that we monitor quantities of drugs and stress the importance of diversion control.

Data gathered in this report conclude younger adults (18 to 25) continue to be more prone to risky substance use as well as poor mental health. Prevention professionals and public health stakeholders must pay close attention to our emerging adult population. As planners, we need to strategize to build awareness within Maine’s young adult population regarding the dangers and long-term risks of substance use. In addition, prevention strategies should continue to address the discrepancy between children’s self-reported behavior and their parent’s perception. Data suggests that protective factors such as strong family and social connections mitigate the risk of substance use behaviors and mental health issues. Our prevention field should embrace interventions and strategies that are focused on fostering communication and trust between adults and youth. Moreover, the understanding and awareness of risk and protective factors can help prevention professionals make decisions about what types of behaviors, attitudes, and norms should be targeted to prevent substance use and misuse. As substance use has been shown to manifest in youth and young adults, it is vital that we intervene before substance use becomes an addiction. This can be accomplished through greater investment in substance use prevention programming and the workforce that supports these efforts.

The relationship between substance use and mental health has been well documented. In Maine and nationwide, comorbidity of substance use and mental illness is quite common. Unfortunately, these issues are still often stigmatized in our society. That is why we must continue to study and understand how the prevalence of one interacts with the other so that prevention and intervention efforts can better address the needs of both. It is critical that we better integrate mental health promotion alongside substance use prevention. Moving farther upstream to provide programming such as social-emotional learning (SEL), which the Maine CDC and Maine Department of Education have invested in during the past two years, will aid communities and youth in the development of skills that promote resiliency and well-being. Skills such as emotion regulation, empathy, personal responsibility, and problem-solving can serve as fundamental protective factors and help prevent the costly outcomes associated with risky substance use and poor mental health.

Finally, for effective prevention planning, we cannot rely on data from a single source to assess the status of problems related to substance use or mental health. In reality, data across multiple sources and systems yield a fuller understanding of behavioral health and the need for prevention. This is why prevention providers are encouraged to consult a wide array of sources of information and include a broad range of stakeholders to give us a more complete picture of the
issue at hand. Similarly, the Maine SEOW emphasizes the alignment and leveraging of efforts and funding across sectors. No single entity in Maine can fix the problems associated with substance use. There are a multitude of interventions and strategies underway throughout our state focused on alleviating the impact of substance use, particularly opioid use. It is vital that these efforts take on a coordinated approach under a shared, unified goal. As the pandemic unfolds and funding becomes more scarce, it is paramount that clear, consistent communication, and strategic collaboration remain a priority in our work.
Public Health District Indicators

The following section highlights key indicators on a Public Health District (PHD) level. Maine has a total of nine public health districts. Eight districts are identified regionally. The ninth district, the Tribal Public Health District, does not have a regional boundary as Maine’s Tribes and American Indian & Alaska Native (AL/AN) populations are located throughout the state. This report does not contain Tribal district-specific data; instead it is comprised of the eight public health districts that cover the entire geography of Maine. The following indicators reflect where a resident lives or where an incident happened and do not distinguish a person’s ethnicity or cultural affiliation.

The establishment of the public health districts was designed to enhance effective and efficient delivery of public health services by:

- Creating the geographic and local framework for greater consistency and equity in statewide delivery of all 10 Essential Public Health Services.
- Providing a consistent basis for regional planning and coordination across the governmental, private (including business), public, and nonprofit sectors.
- Building sustainable infrastructure through regional co-location of Maine CDC and DHHS staff, and through an interactive, fully participatory District Coordinating Council.

The following section will outline several key indicators and similarities and/or differences related to Maine’s PHDs.

---

**KEY INDICATORS AT THE PUBLIC HEALTH DISTRICT LEVEL**

*Key Indicators at the Public Health District Level: Current High-Risk Alcohol Use Among Adults*

**Indicator Description:** This indicator reflects the percentage of adults who reported consuming several alcoholic beverages in a row for at least one day within the past month.\(^{35}\)

**Why Indicator is Important:** Binge drinking is considered a type of high-risk drinking, meaning it increases the risk for many health and social related consequences. High-risk alcohol use has been linked to injury (such as falls, fights, and suicides), violence, crime rates, motor vehicle crashes, stroke, chronic liver disease, addiction, and some types of cancer.

**Data Source(s):** BRFSS, 2014–2017

**Summary:** The highest binge drinking rates continue to be observed among 18 to 35-year-olds, with between one quarter and one third reporting binge drinking within the past month. Rates of binge drinking among adults between 18 and 25 years old ranged from the highest rate (38%) observed in Penquis, to the lowest rate (23%) reported in Aroostook.

*Figure 106. Percent of adults by Public Health District who reported binge drinking in past 30 days by age group: 2014–17*

*Source: BRFSS 2014–17*

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.*

\(^{35}\) BRFSS defines binge drinking as five or more drinks in one sitting for a male and four or more drinks in one sitting for a female.
Key Indicators at the Public Health District Level: Smoking Among Youth

Indicator Description: This indicator illustrates the percentage of Maine high school students who reported smoking a cigarette on at least one occasion within 30 days prior to the survey.

Why Indicator is Important: Use of tobacco is associated with a greater risk of negative health outcomes, including cancer, cardiovascular, chronic respiratory diseases, and can lead to death.

Data Source(s): MIYHS, 2015–2019

Summary: The use of tobacco products among high school students continues to steadily decline. In 2019, seven percent of high school students in Maine reported having smoked a cigarette within the past month. Rates ranged from the highest at nine percent observed in Aroostook, Downeast, and Midcoast to the lowest at six percent in Cumberland and York. With the exception of Downeast, all public health districts observed decreases from 2017 to 2019.

Figure 107. Percent of high school students by Public Health District who reported smoking one or more cigarettes during past 30 days: 2015–2019

Source: MIYHS, 2015 to 2019
Key Indicators at the Public Health District Level: Misuse of Prescription Drugs Among Youth

Indicator Description: This indicator represents the percentage of youth who reported using prescription medications (any type) that were not prescribed to them by a doctor.

Why Indicator is Important: Misuse of prescription drugs may lead to consequences such as unintentional poisonings or overdose, which could lead to death, automobile crashes, addiction, and increased crime.

Summary: On a state level, the percentage of high school students in Maine reporting that they had misused a prescription medication in the past month decreased slightly from 2017 (6%) to 2019 (5%). In 2019, rates did not vary much across public health districts, ranging from three percent in Aroostook to six percent in the Downeast, Midcoast, and Western districts. Rates of prescription drug misuse have remained steady at both the state and district level.

Figure 108. Percent of high school students by Public Health District who have taken prescription drugs not prescribed to them by a doctor (past 30 days): 2015–2019

Source: MIYHS, 2015 to 2019
Key Indicators at the Public Health District Level: Misuse of Prescription Drugs Among Adults

Indicator Description: This measure reflects the percentage of adults in Maine who reported using prescription drugs (any type) not prescribed to them by a doctor or using them in a way other than in which they were prescribed, at least once in their lifetime.

Why Indicator is Important: Misuse of prescription drugs may lead to consequences such as unintentional poisonings, overdose, which may lead to death, dependence and increased crime.

Data Source(s): BRFSS, 2013–2017

Summary: During 2015–17, 4.2 percent of Maine adults reported they had ever misused prescription drugs. Lifetime adult prescription drug misuse rates did not vary much across districts; the lowest rate was observed in Central (2.9%) and the highest rate was seen in Cumberland (5.2%). Western was the only district not to observe an increase from the previous year.

Figure 109. Misuse of prescription drugs among Maine residents (18 and older) in their lifetime, by Public Health District: 2013–15 to 2015–17

Source: BRFSS 2013–15 to 2015–17

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.
Summary: The highest rates of lifetime prescription drug misuse were observed among adults between the ages of 18 and 34. Statewide, nearly one in 10 (9.5%) 18 to 34-year-olds reported misusing prescription drugs within their lifetime. Rates among 18 to 34-year-olds ranged from the lowest in Central (4.2%) to the highest in Cumberland (12.8%).

Source: BRFSS 2014–17

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.
Key Indicators at the Public Health District Level: Babies Born Exposed to/Affected by Substances

Indicator Description: This indicator reflects the number of infants born in Maine where a healthcare provider reported to the Office of Child and Family Services (OCFS) that there was reasonable cause to suspect the baby may either be affected by illegal substance use, demonstrating withdrawal symptoms resulting from prenatal drug exposure (illicit or prescribed), or have fetal alcohol spectrum disorders. This measure potentially excludes instances where the infant was exposed to substances and did not show withdrawal symptoms after birth, instances where the birth of an infant affected by substances was not reported to OCFS, and any other instances in which there were discrepancies between reporters when interpreting the law.36

Why Indicator is Important: Prenatal exposure to alcohol, tobacco, and illicit drugs has the potential to cause a wide spectrum of physical, emotional, and developmental problems for these infants. The harm caused to the child can be significant and long-lasting, especially if the exposure is not detected and the effects are not treated as soon as possible.

Data Source(s): OCFS/MACWIS, 2015–2019

Summary: In 2019, there were 858 notifications submitted to OCFS regarding substance exposed infants; this is a rate of 6.8 notifications per 10,000 residents. Among public health districts, the highest rates were observed in Aroostook (11.8) and Western (10.1) while the lowest rates were observed among Cumberland (2.5) and York (3.8). Aroostook, Penquis, and York public health districts observed increases in rates from 2018 to 2019.

36 MRS Title 22, §4011-B; notification of prenatal exposure to drugs or having fetal alcohol spectrum disorders.

**Key Indicators at the Public Health District Level: Annual Drug-Related Arrest Rate**

**Indicator Description:** This indicator reflects the number of arrests (made by all local and state law enforcement) that were related to drugs per 10,000 people. Drug-related arrests include manufacturing, sales, and possession. The rate per 10,000 allows us to see frequency with which an occurrence shows up within a population over time as well as make relative comparisons between small and large population areas.

Operationalized as: \( \left( \frac{\text{# of drug arrests}}{\text{population}} \right) \times 10,000 \)

**Why Indicator is Important:** Arrest rates for drug sales, manufacturing and drug possession can be an indication of the rate of criminal behavior, but it is important to note that they are also an indication of the level of active law enforcement. Arrest rates are expected to increase with increased enforcement regardless of whether a decline in criminal behavior is observed.

**Data Source(s):** DPS-UCR, 2017–18

**Summary:** In 2017–18, there was an annual average of 16.1 drug-related arrests per 10,000 residents in Maine. During this time, rates among public health districts ranged from 8.5 in Midcoast to 21.1 in Penquis. When broken down by substance type, the highest rates for arrests related to Marijuana were observed among the York and Penquis districts. The highest rates for arrests related to opium, cocaine, and derivatives (e.g., cocaine/crack, heroin) were observed in Aroostook, Cumberland, and Western. The highest rate regarding arrests for other dangerous narcotics (e.g., methamphetamine, benzodiazepines) was observed in the Penquis district. Lastly, the highest rate for drug arrests related to synthetic narcotics (e.g., prescription opiates) was observed in Aroostook. Downeast and Midcoast generally saw lower rates when compared to other districts.

Key Indicators at the Public Health District Level: Overdoses

Indicator Description: This indicator shows the rate of persons receiving help from Emergency Medical Services related to an overdose. Overdose is based on the primary impression given by the emergency responder.

Why Indicator is Important: Overdosing on a substance can cause serious physical harm resulting in hospitalization and even death. Responding to overdoses also uses valuable EMS resources. The rate per 10,000 allows us to see the frequency with which an occurrence happens within a population over time, as well as make relative comparisons between small and large population areas. In this case, the base of 10,000 people was used due to small numbers.

Operationalized as: \( \left( \frac{\text{# of overdose responses}}{\text{population}} \right) \times 10,000 \)

Data Source(s): EMS, 2019

Summary: In 2019, Maine observed 28.3 Emergency Medical Service responses per 10,000 residents due to an alcohol overdose. Over the same period, Maine reported 9.9 EMS responses related to opioids per 10,000 residents.

Source: Emergency Medical Services, 2019
• The public health district with the highest rate of EMS responses due to alcohol overdose was Cumberland (35.3 per 10,000). Aroostook (15.4 per 10,000) and Downeast (17.1 per 10,000) reported the lowest rates of EMS response to alcohol.

Figure 114. Number of overdose EMS responses due to opioids per 10,000 residents, by Public Health District: 2019

Source: Emergency Medical Services, 2019

• The highest rate of EMS responses due to opioid overdose is Penquis public health district (12.9 per 10,000); the public health district with the lowest rate is Midcoast (4.3 per 10,000).
**Key Indicators at the Public Health District Level: Naloxone Administrations**

**Indicator Description:** This indicator shows the number of unique persons receiving naloxone administrations from Emergency Medical Services (EMS) related to an opioid overdose. Naloxone, also known as Narcan, is a medication administered to patients who have experienced an overdose related to an opioid (e.g., prescription painkillers, heroin, or morphine). This indicator includes instances where the opioid overdose is accidental (that is, not a result of intentional or adult misuse). Naloxone is also distributed by many agencies and organizations outside of EMS and not documented here.

**Why Indicator is Important:** Overdosing on a substance can cause serious physical harm resulting in hospitalization and even death. Responding to overdoses also uses valuable medical resources. It is worth stating that this indicator gives us a better sense of the overall prevalence of opioid overdoses, since it includes those that did not result in death.

**Data Source(s):** EMS, 2014–15 to 2018–19

**Summary:** In 2018–19, Maine observed a rate of 10.1 EMS-administered naloxone incidents per 10,000 residents; rates ranged from the highest observed in Penquis (12.6) to the lowest reported in Midcoast (6.5). From 2017–18 to 2018–19, all public health districts except for Aroostook experienced a decrease in the rate of EMS-administered naloxone. Rates in Aroostook have been steadily increasing since 2014–15.

Source: Emergency Medical Services, 2014–15 to 2018–19

*Naloxone, also known as Narcan, is a medication administered to counter the effects of an overdose due to opioids.

**2018-19 data are preliminary
**Key Indicators at the Public Health District Level: Deaths Due to Overdose**

**Indicator Description:** This measure reflects the number of deaths where the cause of death was directly related to the consumption of one or more substances. The measure excludes deaths where a substance may have been ingested prior to engaging in a behavior that resulted in death (e.g., drunk driving) or where lifetime substance use may have impacted health (e.g., alcohol-related cirrhosis). To preserve anonymity and strengthen validity, rates were calculated based on the sum of deaths per three-year interval. The rate per 10,000 allows us to see the frequency with which an occurrence happens within a population over time, as well as make relative comparisons between small- and large-population areas. In this case, the base of 10,000 people was used due to small numbers.

Operationalized as: \( \left( \frac{\text{# of overdose deaths}}{\text{population}} \right) \times 10,000 \)

**Why Indicator is Important:** The most extreme consequences of alcohol and drug use is overdose death, where the substance(s) plays a direct role in an individual’s death. These are potentially preventable deaths. In 2018, 67,367 drug overdose deaths occurred in the United States. The age-adjusted rate of overdose deaths decreased by 4.6 percent from 2017 (21.7 per 100,000) to 2018 (20.7 per 100,000). Opioids—mainly synthetic opioids (other than methadone)—are currently the main contributor in drug overdose deaths. Opioids were involved in 46,802 overdose deaths in 2018 (69.5% of all drug overdose deaths). Two out of three (67.0%) opioid-involved overdose deaths involve synthetic opioids.\(^{37}\)

**Data Source(s):** Dr. Marcella Sorg, Margaret Chase Smith Policy Center at University of Maine, Office of the Chief Medical Examiner, 2013–15 to 2017–19

**Summary:** During 2017–19 (combined years), Maine observed an average of 2.9 drug-related overdose deaths per 10,000 residents per year; rates were highest among the Penquis (3.7), Cumberland (3.4) and Central (3.4) public health districts and lowest among the Aroostook (1.4) and Midcoast (1.8) districts. Central and Cumberland were the only two public health districts to have observed increases in drug related overdose deaths from 2016-18 to 2017-19.

Key Indicators at the Public Health District Level: Perceived Risk of Regular Marijuana Use Among Youth

**Indicator Description:** This measure demonstrates the percentage of individuals who perceive a moderate-to-great risk of harm from smoking marijuana regularly.

**Why Indicator is Important:** High school students who do not believe there is moderate-to-great risk in smoking marijuana regularly are almost seven times as likely to smoke marijuana as their peers who do perceive risk of harm. A similar relationship exists between adult perceptions and consumption.

**Data Source(s):** MIYHS, 2015–2019

**Summary:** In 2019, one out of three (33%) of Maine high school students reported that they felt using marijuana once or twice a week would pose a risk of harm; rates were highest in Aroostook (37%) and lowest in Downeast (30%). Most public health districts, with exceptions of Penquis and Western (remained the same), observed decreases in perception of harm from 2017 to 2019.

Key Indicators at the Public Health District Level: Diagnosis of Anxiety and Depression Among Adults

Indicator Description: This indicator examines the percentage of Maine residents age 18 and older who have ever been told by a doctor that they have a depressive disorder.

Why Indicator is Important: The link between mental health and substance use and misuse is well documented. Experiencing mental health disorders (e.g., anxiety or depression) is associated with higher rates of substance use.38

Data Source(s): BRFSS, 2014–17

Summary: In 2016–17, nearly one-quarter (24%) of adults in Maine reported they had ever been diagnosed with depression. Rates of depression did not vary much across districts and ranged from 21 percent in York to 28 percent in Penquis. Overall, rates of depression among adults in Maine have been relatively stable since 2013–14.

*2017 BRFSS estimates are preliminary, 2018 estimates are expected to be released the Fall of 2020.

Key Indicators at the Public Health District Level: Information Calls for Mental Health and Human Services

Indicator Description: 2-1-1 Maine is a telephone and internet service that provides information and referrals to health and human services. This indicator reflects the number of calls received by 2-1-1 Maine by the type of service requested.

Why Indicator is Important: The data collected from each call provide valuable information, serving as a barometer of health and human service needs in the state.

Data Source(s): 2-1-1 Maine, 2015–2019

Summary: In 2019, there was an average of 22 calls per 10,000 residents made to 2-1-1 Maine seeking resources related to mental health services; rates ranged from the highest observed in Cumberland (34.6) to the lowest in Downeast (10.9) and Aroostook (13.6). Most public health districts remained stable from 2018 to 2019. Cumberland has consistently observed the highest rate over the past several years.

Key Indicators at the Public Health District Level: Rate of Suicide Deaths

Indicator Description: Every death in Maine has a recorded cause. This indicator examines deaths that were classified as a suicide. In this case, a rate per 10,000 residents is used to compare the prevalence across the public health districts.

Why Indicator is Important: Although not the leading cause of death, substance use is often a factor in suicides. For example, the CDC’s National Violent Death Reporting System has estimated that nationally, 14 percent of suicides are attributable to alcohol.  

Data Source(s): DRVS, 2015–17 to 2017–19

Summary: During the 2017–19 period, Maine experienced an average of two suicides per 10,000 residents per year; rates were highest among the Midcoast (2.4) and Central (2.3) public health districts and lowest in Cumberland (1.4) and Aroostook (1.4). Most public health districts, with the exception of Aroostook, observed increases from 2016–18 to 2017–19.
