Reference X-ray Spectra of Metal Foils

The x-ray spectra compiled herein for the following metal foils were recorded at synchrotron beamlines 1-5, 4-2, 7-3 and 10-2 at Stanford Synchrotron Radiation Laboratory (SSRL) using double crystal Si(220) monochromators. The spectra for Ag, Pt and Au were recorded with a double crystal Si(111) monochromator on beamline X-11A at the National Synchrotron Light Source (NSLS) at Brookhaven. All spectra were taken at room temperature in the transmission geometry. In the region ± 50 eV about the absorption edge, each spectrum was scanned in step sizes 0.5 eV. An entrance slit with vertical opening of 1 mm and 0.5 mm was used for Si(220) and Si(111), respectively. The spectrometer resolution in each case was estimated to be 0.5 eV at the K-edge of Ti, and ~ 1.5 eV at the K-edge of Cu. For each element, the tabulated edge energy (Bearden & Burr, *Rev. Mod. Phys.* 39, 125 (1967)) is defined operationally as the first inflection point in the derivative spectrum.

3d Metals: Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Se,
4d Metals: Zr, Nb, Mo, Ru, Pd, Ag, Sn, Sb
5d Metals: Ta, Ir, Pt, Au, Pb.
